Abstract

The Subalpine subregion is a Rocky Mountain altitudinal vegetation zone extending from an elevation of 1575 m to 2175 m at its southernmost occurrence and 1365 m to 2000 m near Grande Cache (Strong 1992). The valley bottoms of the subalpine are extensively utilized for recreational horseback riding and commercial trail riding operations. As a result many of the grass and shrublands around the back country campsites are extensively utilized by horses. This utilization has an impact on the vegetation which can be detrimental to the wildlife populations in the area. Despite the importance of these vegetation types for wildlife and backcountry horse use there is little information on their ecology. The lack of information makes it difficult to development management prescriptions for multiple use. The Alpine subregion which occurs above the upper climatic forest-line in the Rocky Mountains (Strong 1992) overlaps with many of the subalpine community types and therefore can be important locally for wildlife. As a result this guide was developed for the Subalpine and Alpine subregions in order to provide a framework that will easily group the vegetative community types. It is hoped this classification system can be used by field staff to assess the ecology of the sites and develop management prescriptions on lands within each region. This guide represents the analysis of 651 plots described in the Subalpine subregion and 134 grass and shrubland plots described in the Alpine subregion. In the Subalpine subregion it was found there was distinct differences between the grassland and shrubland community types between the Central and Northern Foothills (West of Rocky Mountain house and Hinton), the Central and Northern Rocky Mountains (Banff and Jasper National Parks) and the Southern Rocky Mountains (southwest of Calgary). As a result the Subalpine was prestratified into 3 subdivisions. These types are split into:

Subalpine

Central and Northern Foothills	
A. Native grasslands	17 community types
B. Native shrublands	11 community types
Central and Northern Rocky Mountains	
A Native grasslands	9 community types
B. Native shrublands	8 community types
Southern Rocky Mountains	
A. Native grasslands	19 community types
B. Native shrublands	5 community types
C. Grazed grasslands	9 community types
D. Deciduous	6 community types
E. Conifer	4 community types

Alpine

A. Native grasslands and shrublands	6 community types

The dominant plant species, canopy cover, environmental conditions, response to grazing, forage production and carrying capacity are outlined for each type.

Acknowledgements

The creation of this report would not be possible without the data collected in other projects. We would like to acknowledge Parks Canada for allowing us to use data from the Ecological Land Classification of Banff and Jasper National Parks (Holland and Coen 1982). Much of the grass and shrubland vegetation data collected by Ian Corns and Peter Achuff for this project were incorporated into this guide. We would also like to acknowledge the Alberta Conservation Association and Corporate Management Service. They provided funding for the study of bighorn sheep winter range in Southern Alberta and backcountry horse use and elk carrying capacity in the Panther Corners. The vegetation data from these studies were also included in this guide. Finally appreciation and thanks go out to all members and former members of Land and Forest Service who were involved in data collection.

Introduction

The province of Alberta is covered by a broad spectrum of vegetation regions from prairie in the South, to alpine vegetation in the mountains and dense forests in the Central and Northern part of the province. These broad vegetation regions have been classified into 6 regions and 20 subregions (Dept. of Environmental Protection 1994). Each of the 20 subregions consists of groups of plant communities which are influenced by environmental conditions and human impacts. Intensive management of these regions requires the ability to recognize the vegetative communities that have similar productivities and respond to disturbance in the same way.

The purpose of this guide was to develop a framework that would easily group the grassland and shrubland community types in the Subalpine and Alpine subregions of the province. Initially the guide was developed to provide a classification system that could be used by the field staff to assess carrying capacity and evaluate range condition on back country areas within the foothills of the Subalpine subregion, but it was realized that these community types were only transitional to subalpine and alpine communities described by Ogilvie (1969) and Corns and Achuff (1982). As a result, their original data was reclassified and added to the more recent data to form a more detailed classification.

It is hoped this classification system can be used by field staff to assess the ecology of the sites and develop management prescriptions on lands within the region. This guide supplements the work done by Beckingham et al. (1996), Beckingham and Archibald (1996) and Archibald et al. (1996) on the forested community types in the Subalpine subregion. Their guides are a good description of the forested community types found within the subregion, but it does not include forage production values and carrying capacities. It also does not provide a description of the native shrubland and grassland communities which are utilized by livestock at the lower elevations in this subregion.

The sections of the guide that describes the Central and Northern Rocky Mountain areas of the Subalpine and the Alpine subregions supplements the work done by Corns and Achuff (1982) in Banff and Jasper National Parks.

Climate

Subalpine subregion

The subalpine subregion is a Rocky Mountain altitudinal vegetation zone with its upper boundary formed by the Alpine subregion, whereas the lower boundary abuts the Montane, Foothills parkland and the Upper Foothills subregions. In Alberta, the subalpine extends from 1525 m to 2175 m at its southernmost occurrence and from 1360 m to 2000 m in the vicinity of Grande Cache (Strong 1992). The subalpine has a cordilleran climate characterized by snowy, cold winters and showery cool summers. Annual precipitation ranges from 329 mm to 916 mm, with maximum precipitation falling during July. The subalpine recieves more precipiatiton during the winter months than any subregion (Strong 1992). The mean summer temperatures averages 9.4 °C and winter temperatures typically average -8.9 °C with December and January being the coldest months. The cold winter temperatures help to maintain the snowpack which

makes this an important watershed area.

The majority of the vegetation is dominated by seral lodgepole pine forests at lower elevations with Engelmann spruce and subalpine fir forests being more common at higher elevations. At timberline dwarf spruce, subalpine and whitebark pine are typical of the transition to the Alpine subregion. Imperfectly drained bottomlands are dominated by willow, bog birch, sedge, tufted hairgrass and california oatgrass species and the steep south facing slopes are often dominated by fescue, hairy wildrye, wheatgrass and junegrass species.

Alpine subregion

The Alpine subregion occurs above timberline in the Rocky Mountains of Alberta. Elevationally, alpine occupies areas greater than 2150 m in southern Alberta and declines to 2000 m in more northern portions. It is felt that the total annual precipitation is at least equal to the Subalpine subregion, which potentially makes the Alpine the wettest subregion in Alberta (Strong 1992). Summer temperatures are the coldest in Alberta with July mean temperatures averaging 10 °C. Freezing temperatures occur in all months of the year. Winter temperatures are probably colder than the subalpine subregion with temperatures probably never going above freezing for the whole winter. The cold temperatures help to maintain the snowpack for much of the year. Wind is also extremely important climatic factor in the Alpine. Although, precipitation is abundant the strong winds likely result in very large moisture deficits (Strong 1992).

The Alpine is characterized by low growing vegetation, which helps to protect the vegetation from the dessicating winds, and allows the plants to gain heat from the ground. Glaciers occur at the higher elevations where snow accumulation exceeds melt.

Map 1. Location of Subalpine and Alpine subregions in Alberta

Methods

A community type approach (Mueggler 1988) to classification was chosen in preference to the habitat type approach (Daubenmire 1952) or ecosystem association approach (Corns and Annas 1986) because of the lack of understanding of the successional sequences of the communities. Community types are aggregates of similar plant communities based upon existing floristics regardless of successional status (Mueggler 1988). Community types are what is actually seen in the field. After defining the community types, they then can be linked to the ecosystem associations developed by Corns and Annas (1986) and Beckingham et al. (1996). In the mean time community types can be used as the basis for mapping and range management planning.

Individual plots were initially classified within a forest region using cluster analysis (SAS) and ordination (DECORANA, Gauch 1982). These types were described in individual carrying capacity guides for each forest. This led to differences in classification of the same types between forests, particularly for deciduous forest types. In an effort to standardize the community name and gain some understanding of each community types ecology, all plots sampled in each forest were reclassified. As the study progressed it became quite evident that there were differences in the productivity of the communities between subregions. As a result, it was decided to develop the classification within the subregion framework. A subregion is a geographical area that has broad vegetation zones combined with climatic data. As a result, the vegetation within each subregion is strongly influenced by the climatic conditions.

Sampling for this guide occurred within the Subalpine and Alpine subregions . This guide outlines the preliminary classification of 651 plots described in the Subalpine and 134 plots described in the Alpine subregion.

The procedure for inventory in the Southern Rocky Mtn. and Central and Northern Foothills areas followed the Range Survey Manual (1992) and uses the MF5 form. A plot consisted of a 10x10 m macroplot and ten randomly selected 1x1 m microplots to record the canopy cover of shrubs and ten nested 20x50 cm microplots to record the canopy cover of forbs and grass. At each macroplot a 50x100 cm was clipped and separated into trees, shrubs, forbs and graminoids, oven dried and weighed. The recommended stocking rate is based on 25 percent of the total production for forested types and 50% total production for grass and shrubland types and the fact that one animal requires 455 kg of dry weight material for one month of grazing.

For a description of the methodology for the remaining plots done in the Central and Northern Rocky Mountains of the Subalpine and Alpine subregions see Holland and Coen (1982).

How to use the guide

In the Subalpine subregion it was found there was distinct differences between the grassland and shrubland community types between the Central and Northern Foothills (the foothills west of Sundre, Rocky Mtn. House, Hinton and Grande Cache), the Central and Northern Rocky

Mountains (mountains of Banff and Jasper National Park) and the Southern Rocky Mountains (foothills west of Calgary, Turner valley and areas south of Blairmore) (Strong and Thompson 1995). As a result the Subalpine was prestratified into 3 subdivisions. For the Subalpine first decide which area you are in then turn to the appropriate subdivision in the guide. The Alpine is generally all the vegetation types above timberline.

In order to understand how the community types in this guide are related to the ecosites and ecosite phases outlined in "Ecosites of West-Central Alberta and Southwestern Alberta" (Beckingham et al. 1996, Archibald et al. 1996), the community types in this guide are arranged by ecosite and ecosite phase for West-Central Alberta (Table 1) and Southwestern Alberta (Table 4). **Ecosites** are defined as ecological units that develop under similar environmental influences (climate, moisture and nutrient regime). An **ecosite phase** is a subdivision of the ecosite based on the dominant species in the canopy. Table 1 is a reproduction of Figure 20 in the Ecosites of West-Central Alberta guide and table 4 is a reproduction of Figure 20 in the Ecosites of Southwestern Alberta guide with the community types in this guide highlighted. For the most part the ecosites and ecosite phases are the same, particularly for the forested community types, but a number of new ecosites and ecosite phases had to be created for the grass and shrubland community types (Table 1). The ecosites included (bb)(subxeric/poor) yellow mountain avens, and (dd)(subhygric/medium) bog sedge meadow. The ecosite phases include (b2) bearberry grassland, (bb1) yellow mtn. avens, (c4) hairy wildrye grassland, (d4) California oatgrass, (d5) willow, (d6) grouseberry, (dd1) sedge-bog sedge, (dd2) shrubland, (e3) grass meadow, (g2) willow and (h3) grass bog for West-Central Alberta (Table 1). In Southwestern Alberta the new ecosites include (cc) (submesic/rich) rough fescue, and (i) fen. The ecosite phases included (a2) grassland, (b2) grassland, (c2) yellow mtn. avens, (cc1) rough fescue, (cc2) shrubland, (cc3) forb meadow, (f3) thimbleberry Aw, (f4) shrubby seepages, (i1)shrub fen and (i2) graminoid fen (Table 4). The "Grazing succession" category outlines the successional sequence the community type will undergo with increased grazing pressure. For a detailed description of the forested community types in the Subalpine please refer to the work done by Beckingham et al. (1996), Beckingham and Archibald (1996) and Archibald and Klappstein (1996). The dominant plant species, canopy cover, environmental conditions, response to grazing, forage production and carrying capacity of the grasslands and shrublands for the Subalpine and Alpine subregions are outlined in this guide.

Table 1. Ecosite, ecosite phases and community types for the Subalpine subregion of West-Central Alberta (adapted from Beckingham et al. 1996)(Highlighted communities are described in this guide, non-highlighted communities are outlined in guide to Ecosites of West-Central Alberta)

Drainage: rapid, well
Parent material: M,GF
Soil subgroup:, E.DYB, O.HFP, BR.GL, O.EB

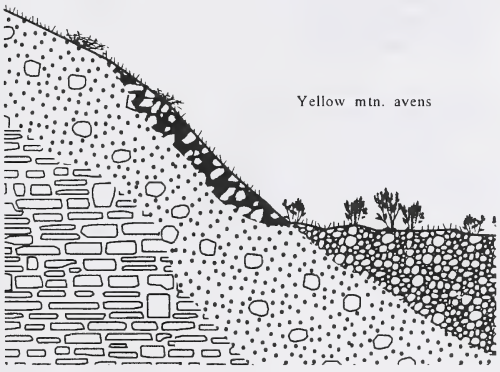
COMMUNITY TYPES

SACMA4. Bearberry-Juniper (n=9)

bb yellow mtn. avens (n=4)

GENERAL DESCRIPTION

This ecosite is located on recent fluvial and glacialfluvial landforms with gentle slopes. The soils are poorly developed gravels and are rapidly drained. Yellow mountain avens, bearberry, juniper and junegrass are typical of these early successional river flats. The poor soil conditions limits the forage productivity and amount of regrowth after grazing. This ecosite should be rated as non-use range.



SUCCESSIONAL RELATIONSHIPS

Yellow mtn. avens generally dominates this community in the early successional stages. Succession in the absence of disturbance will be to balsam poplar, Engelmann spruce and subalpine fir.

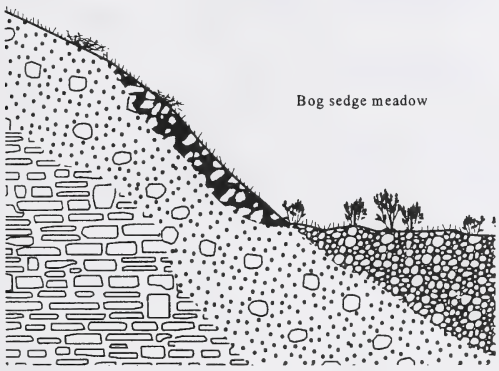
dd bog sedge meadow (n=30)

GENERAL DESCRIPTION

This ecosite is located on moist well drained lowland sites adjacent to rivers and streams at higher elevations in the Central and Northern Foothills of the Subalpine. The presence of bog sedge appears to indicate the transition to the higher Alpine subregion. Indeed, Oglivie (1969) described bog sedge dominated community types on windswept ridges at higher elevations in the Alpine subregion. The forage production of this community is only moderate. Perhaps, the higher elevation and colder climate which favours the growth of bog sedge limits total



productivity of this site.

SUCCESSIONAL RELATIONSHIPS

Due to the nature of the site grasslands often remain the climax vegetation on these sites. In the absence of disturbance willow and bog birch often invade to form willow and bog birch dominated shrublands.

Results

The analysis of the 785 plots distinguished 94 community types. These types were split into 4 categories:

Subalpine

Central and Northern Foothills

A. Native grasslands	17 community types
B. Native shrublands	11 community types

Central and Northern Rocky Mountains

A Native grasslands	9 community types
B. Native shrublands	8 community types

Southern Rocky Mountains

A. Native grasslands	19 community types
B. Native shrublands	5 community types
C. Grazed grasslands	9 community types
D. Deciduous	6 community types
E. Conifer	4 community types

Alpine

A. Native grasslands and shrulands	6 community types

The dominant plant species, canopy cover, environmental conditions, forage production and carrying capacity (when available) are outlined for each community type.

SUBALPINE SUBREGION

SUBALPINE SHRUB AND GRASSLAND ECOLOGY

The Subalpine subregion has highly variable ecological conditions. Much of the variation is the result of complex topography, with a strong ecotonal effect from the surrounding subregions. For instance the grasslands and shrublands of the foothills west of Sundre, Rocky Mtn. House, Hinton and Grande Cache are very similar to the tufted hairgrass, California oatgrass, sedge and rough fescue dominated grass and shrublands of the Upper Foothills subregion. This area is represented by the Central and Northern Foothills, an area dominated by morainal and residuum deposits, gentler slopes (16-45%) and Brunisolic and Luvisolic soils. The Central and Northern Foothills are transitional from the lower Upper Foothills subregion to the higher and steeper Central and Northern Rocky Mountains of the Subalpine subregion. The Central and Northern Rocky Mountains are typical of the morainal and talus deposits on steeper slopes (10-100%), with Brunisolic and Regosolic soils in Banff and Jasper National Parks. These areas are transitional from the lower Subalpine to the higher Alpine subregion. Many species such as bog sedge, heather spp., white mountain avens which are characteristic of alpine communities start to become predominant in these areas. Grasslands on steep, south-facing slopes are dominated by hairy wildrye, junegrass and shrubby cinquefoil.

In southern Alberta (west of Turner valley, south of Blairmore) the subalpine grasslands and shrublands are strongly influenced by the lower Montane subregion. Many of the grass species associated with the Montane (rough fescue, Parry oatgrass, Idaho fescue) dominate the south facing slopes of the Subalpine. These grasslands are very different from the hairy wildrye dominated community types found in the Central and Northern Rocky Mountains. The Southern Rocky Mountains are dominated by residuum, morainal and talus deposits on gentle to steep slopes (16-100%).

SUBALPINE SUBREGION

CENTRAL AND NORTHERN FOOTHILLS

NATIVE GRASSLANDS AND SHRUBLANDS

Figure 1. This figure is typical of the Tufted hairgrass-Sedge community with succession to a Willow-Bog birch dominated community type in the Central and Northern Foothills of the Subalpine subregion.

Native grass and shrubland ecology of the Foothills

The native grass and shrubland community types in the Central and Northern Foothills of the Subalpine subregion (Table 2) are found in the valley bottoms adjacent to streams and rivers. The community types in this area are very similar to the grass and shrublands found in the Upper Foothills subregion and represent a transition from the lower Upper Foothills subregion to the Central and Northern Rocky Mountains of Banff and Jasper National Parks. The sequence of these community types along a moisture gradient from wet (Sedge meadows) to dry south facing slopes (Blunt sedge-Junegrass/Bearberry, Fringed sage/Junegrass-Sedge) is outlined in Figure 2. The change in species composition from the wet sedge meadows to tufted hairgrass, California oatgrass or rough fescue meadows may occur over a 3 foot elevational gradient. The presence of bog sedge (*Kobresia myosuroides*) in the White Mtn. avens-Bog sedge and Sedge-Bog sedge-Tufted hairgrass community types appears to indicate the transition from the lower Central and Northern Foothills to the higher Central and Northern Rocky Mountains. Ogilvie (1969) and Corns and Achuff (1982), described bog sedge dominated community types in the higher elevations of the subalpine and alpine of the Rocky Mountains of Banff and Jasper National Parks.

The maintenance of these grassland community types is extremely fire dependent. The lack of fire quickly allows bog birch and willow to expand shading the modal grassland community types. Prolonged shading causes the understory composition to shift from a tufted hairgrass-California oatgrass dominated understory to a slender wheatgrass-hairy wildrye dominated understory (Figure 2). Under a heavy shrub cover there is little forb or grass cover. Increased shrub cover also causes a decline in forage productivity and reduces the accessiblility for livestock.

Many of these subalpine grass and shrublands are very fragile because of exposure and cold climate. The forage productivity is generally only half of what is found in the lower Upper Foothills subregion and recovery from overgrazing will likely take some time because of the poor growing conditions. As a result grazing by domestic livestock should be done with caution.

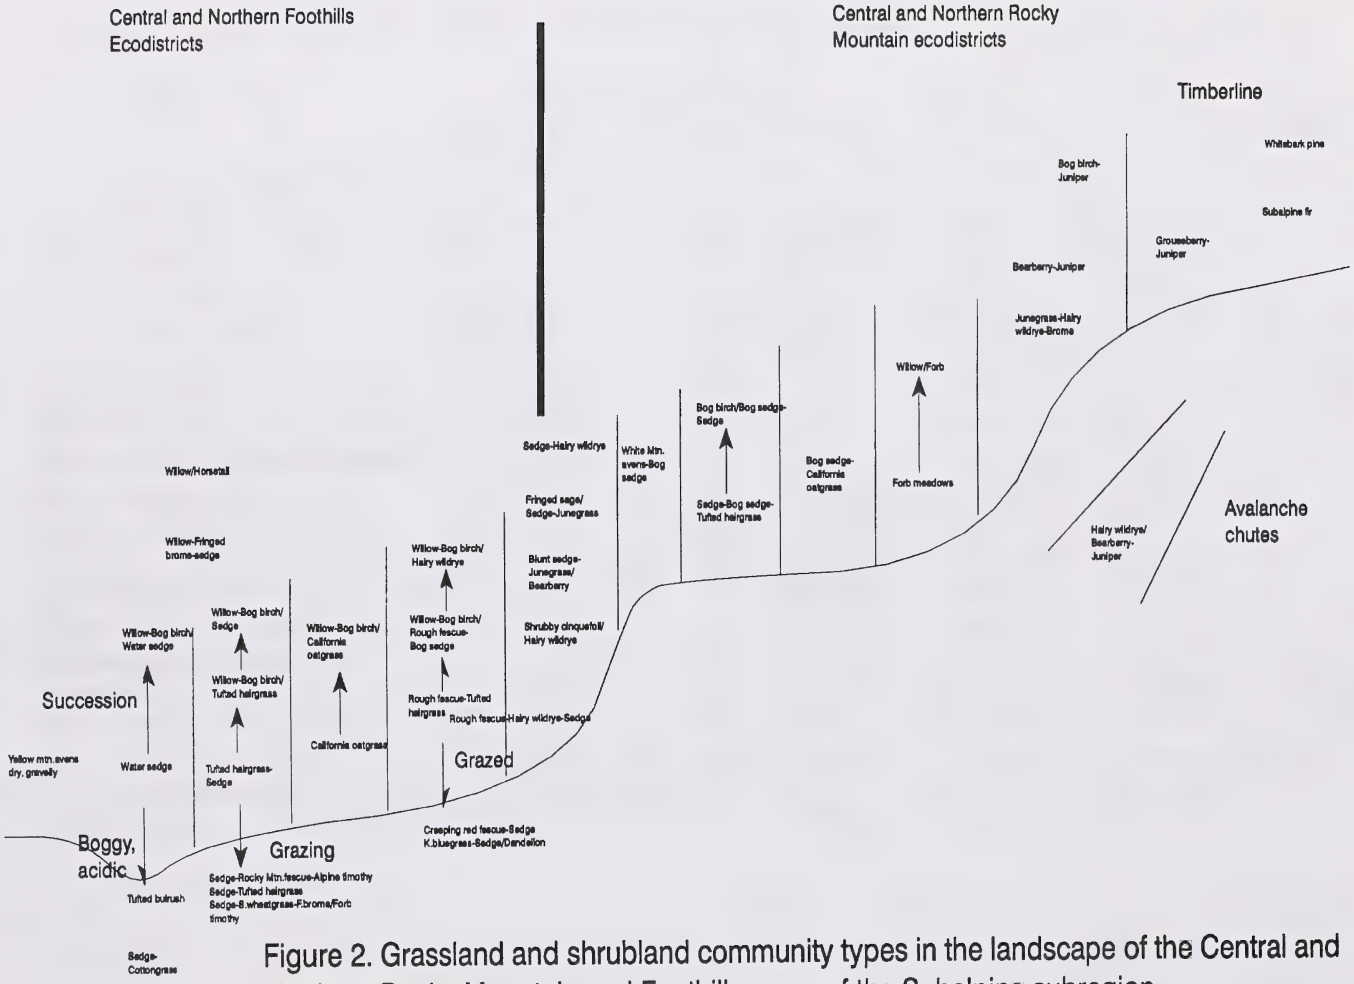

Figure 2. Grassland and shrubland community types in the landscape of the Central and Northern Rocky Mountain and Foothills areas of the Subalpine subregion.

Native grass and shrublands in Central and Northern Mountain and Foothills areas

1. Community above timberline (Alpine subregion).....**Alpine section of guide**
   Community not above timberline, meadows, shrublands or south facing slopes dominated by shrubs and grass..... **2**
2. Moist sites, community dominated by shrubs >20% cover (willow, bog birch) or timberline communities with dwarf trees or grouseberry ..... **see shrub key pg 34**
   Drier to moist sites shrub cover <10% site dominated by grasses and forbs..... **3**
3. Community very wet free standing water, dominated by sedge, cottongrass or tufted bulrush **4**
   Community drier, dominated by tufted hairgrass, rough fescue, california oatgrass, hairy wildrye, juniper or bearberry..... **6**
4. Very wet nutrient rich sites dominated by water or beaked sedge.....**SACFA1**
   Very wet nutrient poor, acidic sites dominated by tufted bulrush and cottongrass..... **5**
5. Site dominated by tufted bulrush.....**SACFA2**
   Site dominated by cottongrass and sedge.....**SACFA3**
6. Grasslands of meadows and lowland areas..... **7**
   Grasslands of south facing slopes, or windswept ridges, hairy wildrye, bearberry, white mtn. avens dominated **20**
7. Higher elevation sites near or at timberline, moist sites dominated by wandering daisy, globeflower, mountain marigold.....**SACMA2**
   Lower elevation sites, valley bottoms adjacent to streams or rivers or if higher elevation dry sites dominated by bog sedge..... **8**
8. Disturbed or grazed community types dominated by Kentucky bluegrass, creeping red fescue, dandelion, alpine bluegrass, alpine timothy or fireweed..... **9**
   Undisturbed community types dominated by rough fescue, California oatgrass, bog sedge, tufted hairgrass, and sedge species..... **14**
9. Moderately grazed site native increasers dominant (slender wheatgrass, sedge, fringed brome, rocky mtn. fescue, alpine timothy), Alpine or Kentucky bluegrass increasing in cover..... **10**
   Heavily grazed sites dominated by Kentucky bluegrass or abandoned airstrips dominated by creeping red fescue or native forb species (fireweed, veiny meadow rue)..... **12**
10. Site dominated by Alpine bluegrass.....**SACMA8**
    Site dominated by rocky mtn. fescue, alpine timothy, sedge, slender wheatgrass, fringed brome (moister sites)..... **11**
11. Site dominated by rocky mtn. fescue, alpine timothy, sedge..... **SACFA6**
    Site dominated by slender wheatgrass, sedge, fringed brome.....**SACFA7**
12. Heavily grazed site dominated by Kentucky bluegrass and dandelion.....**SACFA16**
    Abandoned airstrips dominated by creeping red fescue, or invaded strips dominated by forbs (fireweed, veiny meadow)..... **13**
13 Site dominated by creeping red fescue.....**SACFA15**
   Moister disturbed site dominated by fireweed and veiny meadow rue...**SACFA17**
14. Moist sites dominated by sedge and tufted hairgrass..... **15**
    Drier sites dominated by rough fescue, hairy wildrye, bog sedge, yellow dryas or California oatgrass..... **16**
15. Site dominated by tufted hairgrass, sedge co-dominant.....**SACFA4**
    Site dominated by sedge, tufted hairgrass co-dominant.....**SACFA5**

16. Sites dominated by rough fescue and hairy wildrye.....**SACFA9**
    Sites dominated by California oatgrass, bog sedge, or yellow dryas..... **17**
17. Gravelly river flats dominated by yellow dryas.....**SACMA9**
    Meadow areas dominated by California oatgrass and/or bog sedge..... **18**
18. Site dominated by bog sedge and california oatgrass..... **19**
    Site dominated by california oatgrass and sedge, bog sedge not present.....**SACFA8**
19. Site dominated by bog sedge, california oatgrass, drier sites.....**SACMA1**
    Site co-dominated by bog sedge, tufted hairgrass, and sedge moister sites... **SACFA13**
20. Lower elevation grasslands in the Foothills of the Subalpine..... **21**
    Higher elevation grasslands in the mountains of the Subalpine..... **22**
21 Northern wheatgrass dominated site.....**SACMA7**

Fringed sage, sedge and junegrass dominated slope.....**SACFA12**
22. Avalanche slopes dominated by hairy wildrye, juniper, and bearberry....**SACMA6**
Drier sites or windswept ridges dominated hairy wildrye, juniper, bearberry, shrubby cinquefoil, white mtn. avens..... **23**
23. Windswept ridges dominated by white mtn. avens.....**SACFA14**
South facing slopes dominated by hairy wildrye..... **24**
24. Shallow rocky soils with little grass cover, site dominated by bearberry.. **SACMA4**
Deeper soils, good grass cover dominated by hairy wildrye, junegrass..... **25**
25. Shrubby cinquefoil dominant in stand.....**SACMA3**
Grass cover extensive, dominated by hairy wildrye, junegrass, and brome....**SACMA5**

Shrub dominated communities

1. Timberline communities dominated by whitebark pine, subalpine fir, grouseberry, or willow communities with marsh marigold, wandering daisy or globeflower in understory..... **2**
Riparian communities adjacent to streams or rivers..... **5**
2. Trees present in community (whitebark pine, subalpine fir) or grouseberry dominated.... **3**
Moist seepage areas at treeline dominated by globeflower, wandering daisy or marsh marigold in understory.....**SACMB6**
3. Trees (subalpine fir, whitebark pine) on site..... **4**
Grouseberry dominated shrubland.....**SACMB7**
4. Whitebark pine present.....**SACMB3**
Subalpine fir present.....**SACMB8**
5. Very wet sites with water sedge or horsetail dominated understories..... **6**
Drier sites with tufted hairgrass, california oatgrass, bog sedge, hairy wildrye, rough fescue Kentucky bluegrass, dandelion dominated understories..... **7**
6. Water sedge dominated understory.....**SACFB1, SACMB1**
Horsetail dominated understory.....**SACFB2**
7. Grazed communities dominated by clover and dandelion in understory..... **SACFB5**
Ungrazed sites dominated by native forbs and grasses in understory..... **8**
8. Shrubland communities on seepage areas on south facing slopes with shallow soils, dominated by bog birch and juniper.....**SACMB5**
Meadows and lowland shrublands dominated by rough fescue, bog sedge, california oatgrass, tufted hairgrass, hairy wildrye or sedge in the understory..... **9**
9. Rough fescue dominates the understory..... **10**
Tufted hairgrass, california oatgrass, bog sedge, sedge, hairy wildrye dominate..... **11**
10. Rough fescue and bog sedge dominate understory higher elevations.....**SACFB10**
Rough fescue dominates, bog sedge not present lower elevations.....**SACFB9**
11. Moister sites with deep fluvial deposits dominated by tufted hairgrass, sedge, or fringed brome in understory..... **12**
Drier sites which are well drained at the surface dominated by hairy wildrye, sedge, bog sedge or california oatgrass in understory..... **14**
12. Tufted hairgrass or sedge dominated understory..... **13**
Fluvial areas with Fringed brome dominated understory, lower elevation.....**SACFB11**
13. Tufted hairgrass dominates understory.....**SACFB4**
Graceful sedge and other sedge species dominate understory.....**SACFB3, SASMB2**
14. Modal sites with hairy wildrye and sedge dominating understory..... **15**
Sites dominated by california oatgrass or bog sedge in understory..... **16**
15. Hairy wildrye dominates understory.....**SACFB7,SACMB3**
Graceful sedge and other sedge species dominate understory.....**SACFB3, SASMB2**
16. California oatgrass dominates understory.....**SACFB6**
Bog sedge dominates understory.....**SACFB8, SACMB4**

SACFA1. Water sedge-Beaked sedge meadows

(Carex aquatilis-Carex rostrata)

n=11 This community type is found in all ecodistricts of the subalpine. Wet conditions and periodic flooding result in the formation of water sedge-beaked sedge meadows. Bog birch and willow will invade into the drier edges of these meadows to form the Willow-bog birch/Water sedge community type.

These community types are quite productive producing nearly 2000 kg/ha of forage, but the high water table in the spring and summer when these meadows are most palatable limits livestock use. A study in the Yukon found that crude protein on these meadows declined from a high of 10% in May to less than 5% in September (Bailey et al. 1992). As a result, these meadows would be rated as secondary or non-use range.

SACFA2. Tufted bulrush

(Scirpus cespitosus)

n=12 This community type occurs on subhydric to hydric, lower subalpine sites (1490-1870 m) on nearly level slopes. Corns and Achuff (1982), described this community type on poorly drained soils in the valleys of Banff and Jasper National Park. The soils are dominated by Terric Mesisols and Orthic Gleysols. They felt this community type was successionally mature.

This community type and the Water sedge-Beaked sedge both occupy poorly drained sites with free standing water, but the dominance of tufted bulrush appears to indicate acidic boggy and peaty sites (Scoggan 1978).

SACFA3. Sedge-Cottongrass

(Carex spp.-Eriophorum spp.)

n=7 Corns and Achuff (1982), described a cottongrass dominated community on hydric sites in the Upper subalpine on level to gentle slopes. They found the cottongrass communities to form on depressional areas where the snow melts late and seepage is recieved throughout the growing season. Cottongrass is also characteristic of muskegs and boggy marshes. It appears that this community is located on better drained areas adjacent to tufted bulrush dominated community type. The high acidity of the soil appears to favour the growth of cottongrass, rush-like sedge and rocky ground sedge over water sedge.

SACFA4. Tufted hairgrass-Sedge

(Deschampsia cespitosa-Carex spp.)

n=18 This community type is located on moist sites that are better drained and slightly drier than the pure sedge meadows. Willoughby(2001), found that tufted hairgrass is a common plant species on lowland sites in the valley bottoms of the Upper Foothills subregion . Willoughby (1992), found when this community type is protected from grazing for 25-30 years, willow and bog birch expand and tufted hairgrass and sedge decline. The decline in graminoid cover also results in a decline in available forage production . Continuous heavy grazing causes hairgrass to decline and the site will be invaded by Kentucky bluegrass and dandelion.

Bork (1994), found this community type to be the most productive type described in Willmore Wilderness park. Forage production averages over 2000 kg/ha and can vary from (800-3300 kg/ha). It is interesting to note that forage production on this community type declines from an average of 2200 kg/ha in the Upper Foothills to 1555 kg/ha in the Subalpine subregion. The shorter growing season and colder climate may account for this change in forage productivity. These community types when located next to backcountry campsites will be utilized by horses.

SACFA5. Sedge-Tufted hairgrass

(Carex spp.-Deschampsia cespitosa)

n=8 This community type was described in the Job Lake, Blackstone-Wapiabi Forest Land Use Zones. These areas are extensively utilized by equestrian backcountry users. This community type appears to develop from moderate to heavy grazing pressure on a Tufted hairgrass-Sedge community. Continued heavy grazing pressure appears to cause a further decline in tufted hairgrass to form the Sedge-Rocky Mtn. fescue-Alpine timothy and Sedge-Slender wheatgrass-Fringed brome/Forb community types. If the seed source becomes available these sites have the potential to be invaded by Kentucky bluegrass, timothy, clover and dandelion if the grazing pressure continues.

SACFA6. Sedge-Rocky Mountain fescue-Alpine timothy

(Carex praegracilis-Festuca saximontana-Phleum alpina)

n=6 This community type appears to arise from grazing of a modal Tufted hairgrass-Sedge community type. The six sites described in this community were all located next to outfitter campsites and had been heavily grazed by horses. The heavy grazing pressure causes tufted hairgrass to decline and allows non-native plants such as Kentucky bluegrass and dandelion to invade onto the site. The heavy grazing pressure also appears to change the moisture regime of the site. Many of the plant species on the site, Rocky mountain fescue, Alpine timothy, Alpine bluegrass, junegrass and hairy wildrye are better adapted to well drained, drier conditions. Perhaps, the removal of litter causes the water to drain away from the site more rapidly. Bork (1994), noticed this on similar sites in Willmore Wilderness park. This community type maybe grazed heavier than the previously described Sedge-Tufted hairgrass community type or it could be drier and the grazing pressure shifts the community to one dominated by more drought resistant species.

SACFA7. Sedge-Slender wheatgrass-Fringed brome/Forbs

(Carex praegracilis-Agropyron trachycaulum-Bromus ciliatus/Forbs)

n=18 This community type appears to arise from grazing of a modal Tufted hairgrass-Sedge community type. All the sites described in this community were found adjacent to outfitter campsites in the Job Lake, Blackstone-Wapiabi forest land use zones. The heavy grazing pressure causes tufted hairgrass to decline and allows sedges, slender whatgrass and fringed brome to increase. This community type maybe slightly moister than the previously described Sedge-Rocky mountain fescue-Alpine timothy community. As a result there is succession to more mesic loving plants rather than the drought tolerant plants described in the previous community type.

SACFA8. California oatgrass-Sedge

(Danthonia californica-Carex spp.)

n=5 This community is very similar to a community type described by Willoughby(2001) in the Upper Foothills subregion. Corns and Achuff (1982), described a Willow/California oatgrass dominated community type in Banff and Jasper National Park. It appears dry, gravelly or stony soils, with a fluctuating water table support this moderately productive grassland. Small pockets of this community type occur throughout the Subalpine subregion. In the Yukon these small meadows were found to form in depressions which appeared to act as pronounced frost pockets (Bailey et al. 1992). The cold air drainage and poor nutrient quality of the soil limits the forage productivity of these sites.

SACFA9. Rough fescue-Hairy wildrye-Sedge

(Festuca scabrella-Elymus innovatus-Carex spp.)

n=13 This community was described in the Panther Corners Forest Land Use Zone and in Willmore Wilderness Park on level to undulating ridges, terraces and lower slope positions with Orthic Eutric Brunisolic soils. It is very similar to the Rough fescue-Hairy wildrye community described by Willoughby(2001) in the Upper Foothills subregion and the Rough fescue-Wheatgrass-Hairy wildrye community described by Morgantini and Russell (1983) on Ribbon flats just north of the Panther Corners. This community type is moderately productive and one of the most important communities for wintering elk (Morgantini and Russell 1983). An examination of winter elk diets found that rough fescue made up 45 to 60% of their food intake during the months of December, January and March (Morgantini and Russell 1983). Care must be taken that this community type is not over-utilized by horses and that sufficient forage is left for overwintering elk.

SACFA10. Sedge-Hairy wildrye

(Carex spp.-Elymus innovatus)

n=13 This community was described in the Panther Corners Forest Land Use Zone on steep west and south facing slopes at higher elevations. It occupies sites that are similar to the Fringed sage/Sedge-Junegrass community, but this community type is found at elevations averaging over 2000 meters. This community type is similar to the hairy wildrye dominated communities described by Corns and Achuff (1982) at higher elevations in the subalpine of the Central Mountains ecodistrict (SACMA,4,5,6). This community type was only lightly utilized by elk. In contrast the lower elevation Fringed sage/Sedge-Junegrass exhibited signs of heavy elk use. The higher elevation of this community may limit access to wildlife in this area. It is possible that if this community type was heavily grazed it may resemble the Fringed sage/Sedge-Junegrass community described at lower elevations.

SACFA11. Blunt sedge-Junegrass/Bearberry

(Carex obtusata-Koeleria macrantha/Arctostaphylos uva-ursi)

n=3 This community type occurs on steep south facing slopes, with shallow soils, overlying sandstone bedrock. The majority of the vegetation are composed of drought tolerant species bearberry and junegrass. The inaccessibility and fragile nature of the soils make this community type unsuitable for grazing. This community is very similar to the Junegrass/Sage community described by Willoughby(2001) in the Upper Foothills subregion and the Low northern Sedge/Bearberry community described by Lane et al. (2000) in the Lower Foothills subregion on the south facing slopes of the Athabasca River valley.

SACFA12. Fringed sage/White scaled sedge-Junegrass

(Artemisia frigida/Carex xerantica-Koeleria macrantha)

n=5 This community type occurs on steep south facing slopes, with shallow soils. It is very similar to the previously described Sedge-Junegrass/Bearberry community type, but lacks the cover of bearberry. The lack of bearberry cover in this community type may indicate that the soils of this type are better developed and slightly moister. The inaccessibility and fragile nature of the soils make this community type unsuitable for domestic livestock grazing. This community type is important winter habitat for migrating elk. The steepness of the slope and the southerly aspect limit snow accumulation and allows access to the forage supply. This community is very similar to the Junegrass/Sage community described by Willoughby(2001) in the Upper Foothills subregion.

ENVIRONMENTAL VARIABLES

SACFA13. Sedge-Bog sedge-Tufted hairgrass

(Carex praegracilis-Kobresia myosuroides-Deschampsia cespitosa)

n=6 This community type is found on moist lowland sites at higher elevations in the Central and Northern Foothills. The presence of bog sedge appears to indicate the transition to the higher Alpine subregion . Indeed, Ogilvie (1969) described bog sedge dominated community types at higher elevations in the Alpine subregion.

The presence of bog sedge may also represent the transition between the foothills ecodistricts to the rocky mountain ecodistricts. Corns and Achuff (1982), described bog sedge dominated community types in the Subalpine subregion of Banff and Jasper National Parks.

The forage production on this community type is only moderate. Perhaps, the higher elevation and colder climate which favours the growth of bog sedge limits the total productivity of the site. Camping and grazing of these communities by horses should be restricted.

SACFA14. White mountain avens/Bog sedge

(Dryas integrifolia/Kobresia myosuroides)

n=3 This community type occupies shallow, stoney, wind exposed sites. It represents the transitional community between the bog sedge and white mountain avens community types described by Ogilvie (1969) and Corns and Achuff (1982) on windswept ridges in the Alpine and Subalpine subregions of the Rocky Mountains. The microsite conditions are very similar to higher elevation sites in the Rocky Mountains allowing this community to form in the lower Central Foothills.

The poor soil conditions limits the forage productivity and amount of regrowth after grazing. Often this community type is important winter range for bighorn sheep, because this community type remains snow free for much of the winter.

SACFA15. Creeping red fescue-Sedge

(Festuca rubra-Carex spp.)

n=1 This community type was described in the Blackstone-Wapiabi forest land use zone. It represents an old wellsite road that has been seeded to creeping red fescue. The creeping red fescue was probably used as the reclamation seed to stabilize the road from erosion. Presently, it is the recommendation of the forest service to use native seed in reclamation of these areas in the backcountry. Many of these agronomic mixes are highly invasive on the surrounding vegetation and there is the potential to introduce noxious weeds.

SACFA16. Kentucky bluegrass-Sedge/Dandelion

(Poa pratensis-Carex spp./Taraxacum officinale)

n=1 This community type was described in the Job Lake forest land use zone. It represents a Tufted hairgrass-Sedge meadow that has been heavily grazed for a prolonged period of time. As a result there has been a decline in tufted hairgrass and other native plant species and an invasion of Kentucky bluegrass and dandelion. This community type is uncommon in the backcountry areas because of the lack of seed source for Kentucky bluegrass and dandelion. However, once established it is very competitive and will likely remain on the site. Kentucky bluegrass is very productive, but it quickly loses it nutrient quality in the dormant season. This loss of nutrient quality will impact wildlife utilizing the area.

SACFA17. Fireweed-Meadow rue/Sedge

(Epilobium angustifolium-Thalictrum venulosum/Carex spp.)

n=1 This community type was described in the Panther Corners forest land use zone adjacent to an abandoned air strip. The site was a moist site with a higher nutrient regime making it highly productive. This community type had not been extensively utilized by horses or wildlife and appears to be undergoing succession to a shrub dominated community type. Some invasion of agronomic species (smooth brome, bluegrass spp.) has occurred off the old airstrip into this community type.

SACFB1. Willow-Bog birch/Water sedge

(Salix spp.-Betula glandulosa/Carex aquatilis)

n=9 This shrub community appears on areas with very poor drainage. It is found in association with the wetter water sedge meadows. These sites are fairly productive but difficult to graze due to the moist ground conditions and heavy shrub cover which reduces access and mobility within the area. Increased flooding and prolonged waterlogging may result in the disappearance of willow and a transition to a water sedge meadow.

This community is similar to the water sedge-beaked sedge community in that it is found throughout the foothills and into the mountains. It maybe found in the Upper Foothills, Subalpine and lower Alpine subregions.

SACFB3. Willow/Graceful sedge

(Salix spp./ Carex praegracilis)

n=6 This community type appears to represent a stage of succession onto tufted hairgrass meadows. When these communities are protected from disturbance (fire and grazing) willow and bog birch expand and tufted hairgrass declines. Willow growth also appears to favour the growth of tall forbs (veiny meadow rue, fireweed, aster) and slender wheatgrass. Fire has played a dominant role in controlling brush encroachment in the past and continued protection will allow continued shrub expansion, resulting in a decline in forage production.

SACFB4. Willow-Bog birch/Tufted hairgrass

(Salix glauca-Betula glandulosa/Deschampsia cespitosa)

n=14 This community type is found in association with the Tufted hairgrass-Sedge c.t.. Willow encroachment into a tufted hairgrass meadow eventually results in this community type. Historically fire has played an important role in the maintenance of the grassland community type in this ecoregion. Continued fire suppression will eventually allow willow and bog birch to invade many of these grassy meadows.

Willoughby (1998) found that the encroachment of willow into the Tufted hairgrass-Sedge c.t. caused a decline in forage production from 2200 kg/ha to 1800 kg/ha in the Upper Foothills subregion. This community has a high cover of willow and very little forage for domestic livestock.

SACFB5. Willow-Bog birch/Clover-Dandelion

(Salix glauca-Betula glandulosa/Trifolium repens-Taraxacum officinale)

n=1 This community type represents a Willow-Bog birch/Tufted hairgrass community that has been extensively grazed by horses. This community was described near a historic campsite in the South Ram river drainage. Long-term moderate grazing pressure or heavy grazing pressure over a couple of years causes tufted hairgrass to decline and allows sedge, slender wheatgrass, Kentucky bluegrass, clover and dandelion to increase (Willoughby 2001) These community types are highly productive for domestic livestock throughout the growing season, but the poor quality of Kentucky bluegrass, clover and dandelion, particularly, in the dormant season limits the use of these community types for wildlife.

SACFB6. Willow-Bog birch/California oatgrass

(Salix glauca-Betula glandulosa/Danthonia californica)

n=19 This community type likely develops from willow encroaching onto an oatgrass dominated meadow. The oatgrass meadows are found on dry, gravelly soils. These meadows may also form in frost pockets. The spread of willow is likely caused by lack of natural disturbance, such as fire. The cover of willow on this community type is fairly extensive. This will restrict access to domestic livestock. This community type would be rated as secondary range.

SACFB7. Willow-Bog birch/Hairy wildrye

(Salix glauca-Bog birch/Elymus innovatus)

n=20 This community is typical of the valley bottoms where the low temperatures prohibit the growth of trees. Corns and Achuff (1982) described a similar community in the Banff and Jasper National Parks. They found this community type occupied coarse stream deposits which had repeated flooding.

Bork (1994) felt this community type developed from the invasion of willow and bog birch onto grasslands in the absence of disturbance in Willmore Wilderness park. Willow cover has increased, shading the growth of grasses and allowing tall-growing forbs, such as fireweed, aster and veiny meadow rue to increase. He felt continued protection from disturbance will allow succession to shrub and eventually tree species, which will increase shading of the understory vegetation and eventually lower forage production.

SACFB8. Bog birch/Bog sedge-Sedge

(Betula glandulosa/Kobresia myosuroides-Carex spp.)

n=5 This community type was described on moist lowland sites at higher elevations in the Central and Northern foothills ecodistricts. It appears this community type originated from recent shrub encroachment onto sedge-bog sedge-tufted hairgrass community type. The presence of bog sedge may represent the transition between the foothills ecodistricts and the rocky mountain ecodistricts. Corns and Achuff (1982) described bog sedge dominated community types in the Central and Northern Rocky Mountains of the Subalpine subregion of Banff and Jasper National Parks. Camping and grazing of these communities by horses should be restricted.

SACFB9. Bog birch-Willow/Rough fescue

(Betula glandulosa-Salix spp./Festuca scabrella)

n=4 This community type is very similar to the Bog birch/Rough fescue-Sedge community described by Willoughby (1992) in the Upper Foothills subregion. Willoughby found that the rough fescue grasslands were located upslope of tufted hairgrass meadows on slightly drier, gravelly soils. Bork (1994), also described rough fescue dominated grasslands in Willmore Wilderness Park. This community type is also similar to the Bog birch/Rough fescue-Bog sedge community type but lacks the cover of bog sedge. Bog sedge tends to grow at higher elevations and appears to indicate the transition from the Upper Foothills subregion to the Subalpine subregion.

It appears the lack of fire on this community type has allowed the shrub cover to expand, reducing forage productivity for wildlife and domestic livestock. In one study, burning a Bog birch/Rough fescue community type twice in 3 year intervals controlled birch growth and increased total forage production by over 40% compared to the unburned control in the Upper Foothills subregion (Bork 1990).

SACFB11. Willow/Fringed brome-Sedge

(Salix barclayi/Bromus ciliatus-Carex spp.)

n=1 This community was described on the banks of Forbidden Creek west of Rocky Mtn. House where the water table is high but flooding is rare. It occupies the fluvial terraces along the creek . A similar community type Willow/Fringed brome-Slender wheatgrass was described in the Lower Foothills subregion (Lane et al. 2000). The production of the Lower Foothills type averaged over 1700 kg/ha. This community type had only half the production (760 kg/ha). The more extreme climatic conditions of this site in the subalpine likely limits the growth of forage.

SUBALPINE SUBREGION

CENTRAL AND NORTHERN ROCKY MOUNTAINS

NATIVE GRASSLANDS AND SHRUBLANDS

Figure 3. The presence of bog sedge in this Willow-Bog birch/Bog sedge community indicates the transition to the higher and steeper Central and Northern Rocky Mountains of the Subalpine subregion. Note the transition from the Subalpine to Alpine subregions in the background.

Native grass and shrubland ecology Mountain ecodistricts

The native grass and shrubland community types in the Central and Northern Rocky Mountains of the Subalpine subregion (Table 3) are found in the valley bottoms adjacent to streams and rivers. The tufted hairgrass, California oatgrass and rough fescue dominated community types described previously in the foothills can also be found in the mountains, but these grassland community types are more common in the foothills and therefore were described in that section of the guide.

There are a number of grassland community types in the Central and Northern Rocky Mountains which are unique and appear to represent a transition from the lower subalpine mountain ecodistricts to the Alpine subregion. These include the hairy wildrye, junegrass and shrubby cinquefoil dominated community types (SACMA3,4,5,6) which are found on steep south facing slopes, at higher elevations throughout the mountains (Figure 2). Near timberline there is a unique forb dominated (globeflower,wandering daisy, mountain marigold, mountain heliotrope) community type found on imperfectly to well drained sites. The presence of bog sedge (*Kobresia myosuroides*) in the Bog sedge-California oatgrass community type appears to indicate the transition from the lower Central and Northern Rocky Mountains to the Alpine subregion. Ogilvie (1969) and Corns and Achuff (1982), described bog sedge dominated community types in the higher elevations of the subalpine and alpine of the Rocky Mountains of Banff and Jasper National Parks.

The maintenance of the grassland community types in the mountains is extremely fire dependent. The lack of fire quickly allows bog birch and willow to expand shading the modal grassland community types. Prolonged shading causes the understory composition to shift from a tufted hairgrass-California oatgrass dominated understory to a slender wheatgrass-hairy wildrye dominated understory. Under a heavy shrub cover there is little forb or grass cover. The sequence of the grassland and shrubland community types unique to the mountain ecodistricts is outlined in figures 2 and 4. These figures represent the transition from willow, bog birch dominated communities in the valley bottoms to the grass and dwarf shrublands in the upper Subalpine and Alpine subregions.

Many of these subalpine grass and shrublands are very fragile because of exposure and cold climate. The forage productivity is generally only half of what is found in the lower Upper Foothills subregion and recovery from overgrazing will likely take some time because of the poor growing conditions. As a result grazing by domestic livestock should be done with caution.

Table 3. Native grass and shrublands of the Central and Northern Rocky Mountain ecodistricts of the Subalpine subregion

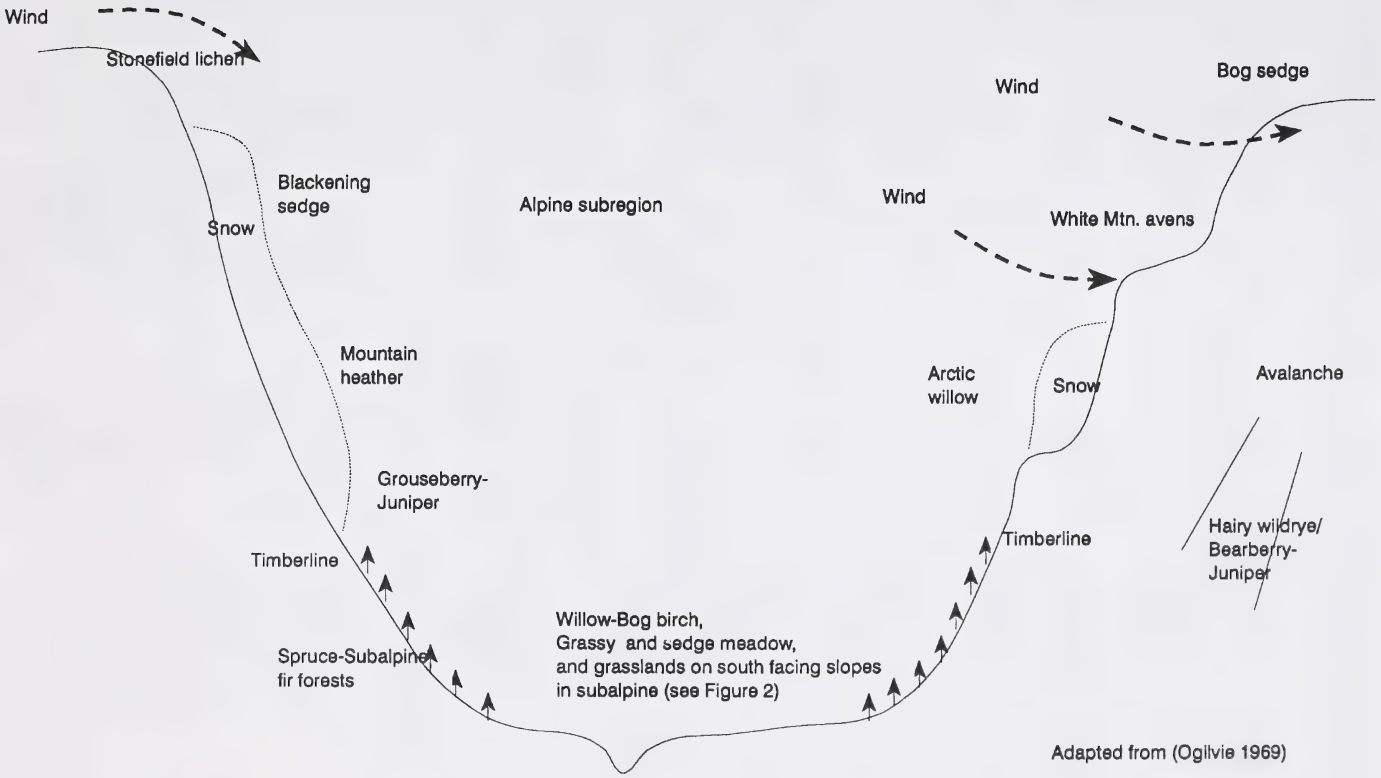

Figure 4. Sequence of plant communities in the Alpine subregion of Alberta.

Native grass and shrublands in Central and Northern Mountain and Foothills areas

1. Community above timberline (Alpine subregion).....**Alpine section of guide**
   Community not above timberline, meadows, shrublands or south facing slopes dominated by shrubs and grass..... **2**
2. Moist sites, community dominated by shrubs >20% cover (willow, bog birch) or timberline communities with dwarf trees or grouseberry ..... **see shrub key pg 34**
   Drier to moist sites shrub cover <10% site dominated by grasses and forbs..... **3**
3. Community very wet free standing water, dominated by sedge, cottongrass or tufted bulrush **4**
   Community drier, dominated by tufted hairgrass, rough fescue, california oatgrass, hairy wildrye, juniper or bearberry..... **6**
4. Very wet nutrient rich sites dominated by water or beaked sedge.....**SACFA1**
   Very wet nutrient poor, acidic sites dominated by tufted bulrush and cottongrass..... **5**
5. Site dominated by tufted bulrush.....**SACFA2**
   Site dominated by cottongrass and sedge.....**SACFA3**
6. Grasslands of meadows and lowland areas..... **7**
   Grasslands of south facing slopes, or windswept ridges, hairy wildrye, bearberry, white mtn. avens dominated **20**
7. Higher elevation sites near or at timberline, moist sites dominated by wandering daisy, globeflower, mountain marigold.....**SACMA2**
   Lower elevation sites, valley bottoms adjacent to streams or rivers or if higher elevation dry sites dominated by bog sedge..... **8**
8. Disturbed or grazed community types dominated by Kentucky bluegrass, creeping red fescue, dandelion, alpine bluegrass, alpine timothy or fireweed..... **9**
   Undisturbed community types dominated by rough fescue, California oatgrass, bog sedge, tufted hairgrass, and sedge species..... **14**
9. Moderately grazed site native increasers dominant (slender wheatgrass, sedge, fringed brome, rocky mtn. fescue, alpine timothy), Alpine or Kentucky bluegrass increasing in cover..... **10**
   Heavily grazed sites dominated by Kentucky bluegrass or abandoned airstrips dominated by creeping red fescue or native forb species (fireweed, veiny meadow rue)..... **12**
10. Site dominated by Alpine bluegrass.....**SACMA8**
    Site dominated by rocky mtn. fescue, alpine timothy, sedge, slender wheatgrass, fringed brome (moister sites)..... **11**
11. Site dominated by rocky mtn. fescue, alpine timothy, sedge..... **SACFA6**
    Site dominated by slender wheatgrass, sedge, fringed brome.....**SACFA7**
12. Heavily grazed site dominated by Kentucky bluegrass and dandelion.....**SACFA16**
    Abandoned airstrips dominated by creeping red fescue, or invaded strips dominated by forbs (fireweed, veiny meadow)..... **13**
13 Site dominated by creeping red fescue.....**SACFA15**
   Moister disturbed site dominated by fireweed and veiny meadow rue...**SACFA17**
14. Moist sites dominated by sedge and tufted hairgrass..... **15**
    Drier sites dominated by rough fescue, hairy wildrye, bog sedge, yellow dryas or California oatgrass..... **16**
15. Site dominated by tufted hairgrass, sedge co-dominant.....**SACFA4**
    Site dominated by sedge, tufted hairgrass co-dominant.....**SACFA5**

16. Sites dominated by rough fescue and hairy wildrye.....**SACFA9**
    Sites dominated by California oatgrass, bog sedge, or yellow dryas..... **17**
17. Gravelly river flats dominated by yellow dryas.....**SACMA9**
    Meadow areas dominated by California oatgrass and/or bog sedge..... **18**
18. Site dominated by bog sedge and california oatgrass..... **19**
    Site dominated by california oatgrass and sedge, bog sedge not present.....**SACFA8**
19. Site dominated by bog sedge, california oatgrass, drier sites.....**SACMA1**
    Site co-dominated by bog sedge, tufted hairgrass, and sedge moister sites... **SACFA13**
20. Lower elevation grasslands in the Foothills of the Subalpine..... **21**
    Higher elevation grasslands in the mountains of the Subalpine..... **22**
21 Northern wheatgrass dominated site.....**SACMA7**

Fringed sage, sedge and junegrass dominated slope.....**SACFA12**

22. Avalanche slopes dominated by hairy wildrye, juniper, and bearberry....**SACMA6**
    Drier sites or windswept ridges dominated hairy wildrye, juniper, bearberry, shrubby cinquefoil, white mtn. avens..... **23**
23. Windswept ridges dominated by white mtn. avens.....**SACFA14**
    South facing slopes dominated by hairy wildrye..... **24**
24. Shallow rocky soils with little grass cover, site dominated by bearberry.. **SACMA4**
    Deeper soils, good grass cover dominated by hairy wildrye, junegrass..... **25**
25. Shrubby cinquefoil dominant in stand.....**SACMA3**
    Grass cover extensive, dominated by hairy wildrye, junegrass, and brome....**SACMA5**

Shrub dominated communities

1. Timberline communities dominated by whitebark pine, subalpine fir, grouseberry, or willow communities with marsh marigold, wandering daisy or globeflower in understory..... **2**
   Riparian communities adjacent to streams or rivers..... **5**
2. Trees present in community (whitebark pine, subalpine fir) or grouseberry dominated.... **3**
   Moist seepage areas at treeline dominated by globeflower, wandering daisy or marsh marigold in understory.....**SACMB6**
3. Trees (subalpine fir, whitebark pine) on site..... **4**
   Grouseberry dominated shrubland.....**SACMB7**
4. Whitebark pine present.....**SACMB3**
   Subalpine fir present.....**SACMB8**
5. Very wet sites with water sedge or horsetail dominated understories..... **6**
   Drier sites with tufted hairgrass, california oatgrass, bog sedge, hairy wildrye, rough fescue Kentucky bluegrass, dandelion dominated understories..... **7**
6. Water sedge dominated understory.....**SACFB1, SACMB1**
   Horsetail dominated understory.....**SACFB2**
7. Grazed communities dominated by clover and dandelion in understory..... **SACFB5**
   Ungrazed sites dominated by native forbs and grasses in understory..... **8**
8. Shrubland communities on seepage areas on south facing slopes with shallow soils, dominated by bog birch and juniper..... .....**SACMB5**
   Meadows and lowland shrublands dominated by rough fescue, bog sedge, california oatgrass, tufted hairgrass, hairy wildrye or sedge in the understory..... **9**
9. Rough fescue dominates the understory..... **10**
   Tufted hairgrass, california oatgrass, bog sedge, sedge, hairy wildrye dominate..... **11**
10. Rough fescue and bog sedge dominate understory higher elevations.....**SACFB10**
    Rough fescue dominates, bog sedge not present lower elevations.....**SACFB9**
11. Moister sites with deep fluvial deposits dominated by tufted hairgrass, sedge, or fringed brome in understory..... **12**
    Drier sites which are well drained at the surface dominated by hairy wildrye, sedge, bog sedge or california oatgrass in understory..... **14**
12. Tufted hairgrass or sedge dominated understory..... **13**
    Fluvial areas with Fringed brome dominated understory, lower elevation.....**SACFB11**
13. Tufted hairgrass dominates understory.....**SACFB4**
    Graceful sedge and other sedge species dominate understory.....**SACFB3, SASMB2**
14. Modal sites with hairy wildrye and sedge dominating understory..... **15**
    Sites dominated by california oatgrass or bog sedge in understory..... **16**
15. Hairy wildrye dominates understory.....**SACFB7,SACMB3**
    Graceful sedge and other sedge species dominate understory.....**SACFB3, SASMB2**
16. California oatgrass dominates understory.....**SACFB6**
    Bog sedge dominates understory.....**SACFB8, SACMB4**

SACMA1. Bog sedge-California oatgrass

(Kobresia myosuroides-Danthonia californica)

n=1 This community type appears to represent the transition from the foothills ecodistricts to the mountain ecodistricts of the subalpine. It appears that tufted hairgrass, california oatgrass and rough fescue all decline and bog sedge increases as there is an increase in elevation and change from the foothills to the mountains.

This community type is found on level to gently sloping valley bottoms with mesic moisture regimes. The presence of California oatgrass maybe indicative of a well drained, gravelly site. In the Yukon the California oatgrass dominated community types were found to form in depressions which appeared to act as pronounced frost pockets (Bailey et al. 1992). Bog sedge also appears to be adapted to these site condition (Oglivie 1969).

SACMA2. Forb meadows

(Trollius albiflorus, Erigeron peregrinus, Anemone occidentalis, Caltha leptosepala)

n=17 These forb dominated meadows include both the Caltha leptosepala-Trollius albiflorus and Erigeron peregrinus-Valeriana sitchensis community types described by Corns and Achuff (1982). These meadows occupy mesic to hygric, gently sloping, upper subalpine to alpine areas. The soils are imperfectly to well drained Gleysols on fluvial and morainal landforms. On the poorly to imperfectly drained sites in areas where snow melts late and seepage is received throughout the growing season mountain marigold and globeflower predominate. In contrast on better drained, drier sites fleabane and mountain heliotrope predominate.

SACMA3. Shrubby cinquefoil/Hairy wildrye

(Potentilla fruticosa/Elymus innovatus)

n=5 Corns and Achuff (1982), described this community type on subxeric to xeric, south facing slopes in Banff and Jasper. The soils are rapidly to well drained Regosols on colluvial, eolian and glacial landforms. On more stable sites they felt succession would be to a Lodgepole pine/Juniper/Bearberry community type.

SACMA4. Bearberry-Juniper

(Arctostaphylos uva-ursi-Juniperus communis)

n=13 This community type is very similar to the previously describe Shrubby cinquefoil/Hairy wildrye dominated community type. Both community types occupy rapidly drained, steep south facing slopes. This community type is distinguished from the Shrubby cinquefoil community type by the presence of a high cover of bearberry and juniper and a low cover of shrubby cinquefoil. This community type is much drier than the shrubby cinquefoil type and is located on much steeper slopes.

SACMA5. Junegrass-Hairy wildrye-Brome

(Koeleria macrantha-Elymus innovatus-Bromus inermis)

n=22 This community type was described by Corns and Achuff (1982) on subxeric, steep south facing slopes in the Front ranges east of Banff and Jasper. It is very similar to the bearberry and shrubby cinquefoil community types previously described, but this community type has better developed soils (Brunisols) than the Regosolic soils of the other community types.

This community type is also similar to the Pasture sagewort/Junegrass and Junegrass-Plains reed grass community types described by Willoughby et al (2003) and Stringer (1973) in the lower Montane subregion and the Junegrass/Sage community type described in the Upper Foothills subregion (Willoughby 2001). The high elevations of this community distinguishes this community type from the lower elevation grasslands (Corns and Achuff 1982).

SACMA6. Hairy wildrye/Bearberry-Juniper

(Elymus innovatus/Arctostaphylos uva-ursi-Juniperus communis)

n=36 Ogilvie (1969) and Corns and Achuff (1982), described this community type on steep south-facing slopes, with stoney, black soils. This community type is also subjected to frequent snow avalanching, particularly during the spring when the snow is melting. This community type is moister than the junegrass, bearberry and shrubby cinquefoil communities previously described. This is likely the result of the increased snow cover. The soils are Melanic Brunisols and Humic Regosols, which are better developed than the drier community types previously described.

SACMA7. Northern wheatgrass

(Agropyron dasystachyum)

n=3 This community type occurs on steep south facing slopes, with shallow soils, at lower elevations in the subalpine. It is very similar to the northern wheatgrass community type described by Willoughby et al. (2003) and Corns and Achuff (1982) in the Montane subregion of Banff and Jasper. This community type is distinguished from the other hairy wildrye, junegrass, bearberry and shrubby cinquefoil community types by the presence of northern wheatgrass and the lower elevations. The inaccessibility and fragile nature of the soils make this community type unsuitable for grazing.

SACMA8. Alpine bluegrass

(Poa alpina)

n=1 The ecology of this community type is unclear. It was described on a gentle, easterly slope in the lower subalpine. Alpine bluegrass is known to grow in meadows, tundra and rocky slopes and is often abundant where the ground has been compacted (MacKinnon et al. 1992). It is possible that this community type could have been described adjacent to a game or hiking trail.

SACMB1. Willow/Water sedge

(Salix spp./Carex aquatilis)

n=23 This shrub community appears on areas with very poor drainage. It is found in association with the wetter water sedge meadows. These sites are fairly productive but difficult to graze due to the moist ground conditions and heavy shrub cover which reduces access and mobility within the area. Increased flooding and prolonged waterlogging may result in the disappearance of willow and a transition to a water sedge meadow.

This community is similar to the water sedge-beaked sedge community in that it is found throughout the foothills and into the mountains. It maybe found in the Upper Foothills, Subalpine and lower Alpine subregions.

SACMB2. Willow-Bog birch/Sedge

(Salix glauca-Betula glandulosa/Carex spp.)

n=21 This community type is found in association with the Tufted hairgrass-Sedge or California oatgrass community type. Willow encroachment into grassland meadows eventually results in this community type. Historically fire has played an important role in the maintenance of the grassland community type in this ecoregion. Continued fire suppression will eventually allow willow and bog birch to invade many of the grassy meadows.

This community type is slightly drier than the Willow/Water sedge dominated community type.

SACMB3. Willow-Bog birch/Hairy wildrye

(Salix glauca-Bog birch/Elymus innovatus)

n=17 This community is typical of the valley bottoms where the low temperatures prohibit the growth of trees. Corns and Achuff (1982) described a similar community in the Banff and Jasper National Parks. They found this community type occupied coarse stream deposits which had repeated flooding.

Bork (1994) felt this community type developed from the invasion of willow and bog birch onto grasslands in the absence of disturbance in Willmore Wilderness park. Willow cover has increased, shading the growth of grasses and allowing tall-growing forbs, such as fireweed, aster and veiny meadow rue to increase. He felt continued protection from disturbance will allow succession to shrub and eventually tree species. This community is typical of the valley bottoms throughout the subalpine in both the foothills and mountain ecodistricts.

SACMB4. Willow-Bog birch/Bog sedge

(Salix spp.-Betula glandulosa/Kobresia myosuroides)

n=14 This community type was described on moist lowland sites at higher elevations in the Central and Northern Rocky Mountain ecodistricts. It appears this community type originated from recent shrub encroachment onto sedge-bog sedge-tufted hairgrass community type. The presence of bog sedge may represent the transition between the foothills ecodistricts and the rocky mountain ecodistricts. Corns and Achuff (1982) described bog sedge dominated community types in the Central and Northern Rocky Mtn. ecodistricts of the Subalpine subregion of Banff and Jasper National Parks.

SACMB6. Willow/Forb

(Salix spp./Trollius albiflorus, Erigeron peregrinus, Mountain heliotrope)

n=6 This community type results from the invasion of willow onto the forb dominated meadows (SACMA2) previously described. These meadows occupy mesic to subhygric, gently sloping, upper subalpine to alpine areas. The soils are imperfectly to well drained Gleysols on fluvial and morainal landforms (Corns and Achuff 1982). On the poorly to imperfectly drained sites in areas where snow melts late and seepage is received throughout the growing season mountain marigold and globeflower predominate. In contrast on better drained, drier sites wandering daisy and mountain heliotrope predominate.

SACMB8. Subalpine fir

(Abies lasiocarpa)

n=22 This is a timberline community type found in conjunction with small patches of the grouseberry-juniper community type. The trees tend to be very small and shrub like. Ogilvie (1969) described timberline as a gradual breaking -up of the forest into groves, tree islands, low stunted krummholz colonies, and finally dwarfed isolated trees. Ogilvie found timberline to occur high on lee slopes and low on wind-exposed slopes, south facing slopes, avalanche slopes, along stream bottoms and on unstable substrata such as scree and rubble. The major environmental factors controlling timberline are low temperature, wind dessication, avalanching and snow depth.

SUBALPINE SUBREGION

SOUTHERN ROCKY MOUNTAINS

NATIVE GRASSLANDS AND SHRUBLANDS

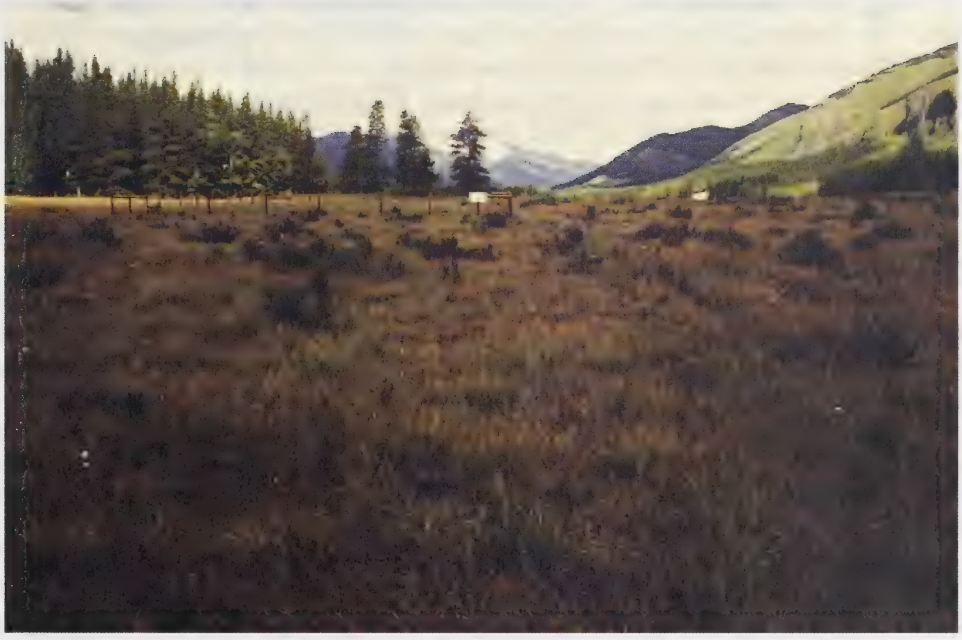

Figure 5. This figure is typical of Rough fescue-Sedge community on mesic sites in the Southern Rocky Mountains of the Subalpine subregion. On steeper slopes rough fescue and hairy wildrye predominate.

Native grass and shrubland ecology of the Southern Rocky Mountains

The ecosites and ecosite phases of the native grass and shrubland community types in the Southern Rocky Mountains of the Subalpine subregion (Table 4) are found in the valley bottoms adjacent to streams and rivers and on south facing slopes. This also includes an area that was classified as Lower Foothills, west of Turner Valley. The grass and shrublands within this area more closely resemble the subalpine than the Lower Foothills.

The grassland and shrubland community types in this ecodistrict are strongly influenced by the lower Montane subregion. Many of the grass species associated with the Montane (rough fescue, Parry oatgrass, Idaho fescue) are associated with the grassland community types described in this ecodistrict. On the wet, imperfectly drained lower slope positions the grass and shrubland communities are very similar to the water sedge and willow/water sedge communities described in the northern ecodistricts. It is the grasslands of the south facing slopes that are different between the southern and northern ecodistricts. In the northern ecodistricts the grasslands of south facing slopes are dominated by hairy wildrye, junegrass and shrubby cinquefoil. In contrast, the grasslands of the southern ecodistrict are dominated by rough fescue, bearberry, hairy wildrye and sedge species.

On gentler south-facing slopes at lower elevations rough fescue and sedge dominate the grassland community types. On more mesic sites within this community Richardson needlegrass may become co-dominant with rough fescue. In contrast at higher elevations on steeper slopes hairy wildrye replaces sedge and Richardson needlegrass as the co-dominant species.

At higher elevations just north of Waterton Lakes National Park the windswept ridges are dominated by Idaho fescue-Junegrass, Bearberry and White mountain avens to form the Fescue-Junegrass/Bearberry and White mountain avens community types. These community types are important wintering areas for bighorn sheep.

Many of these subalpine grass and shrublands are very fragile because of exposure and cold climate. The forage productivity is generally only half of what is found in the lower Montane subregion and recovery from overgrazing will likely take some time because of the poor growing conditions. Grazing pressure causes rough fescue to decline and allows sedge and hairy wildrye to dominate the community. On moist sites heavy grazing pressure allows Kentucky bluegrass to invade.

The carrying capacity, moisture and nutrient regime of the grass and shrubland communities found in the Southern Rocky Mountains of the Subalpine subregion are outlined in Table 5.

Table 4. Ecosites, ecosite phases and community types for the Subalpine subregion in Southwestern Alberta (adapted from Archibald et al. 1996)(highlighted communities are described in this guide, non-highlighted communities are outlined in guide to Ecosites of Southwestern Alberta)

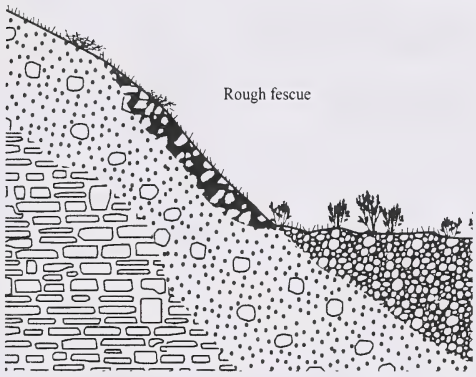
GENERAL DESCRIPTION

This ecosite is typical of south and west facing slopes and lower slope positions throughout the southern mountains of the Subalpine subregion from an elevation of 1500 m to 1900 m. This ecosite is usually dominated by grass species because of the dry site conditions and westerly winds. The soils of this ecosite are dominated by deep black soils. A number of rough fescue dominated sites have not had the species composition change in over 30 years of no disturbance in the Montane subregion indicating the climax nature of this ecosite.

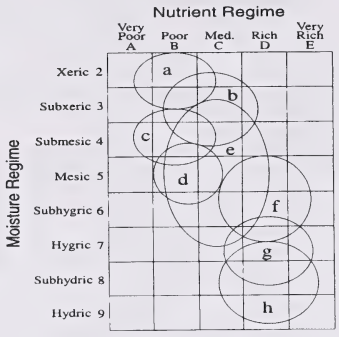


SUCCESSIONAL RELATIONSHIPS

Due to the nature of the site grasslands often remain the climax vegetation on these sites. On moister sites shrubs and trees such as saskatoon, snowberry, chokecherry and aspen often invade the site. Heavy grazing pressure on these grasslands can often lead to a degraded site that is dominated by Kentucky bluegrass, timothy and clover species.

INDICATOR SPECIES

rough fescue	Kentucky bluegrass
Parry oatgrass	Timothy
Idaho fescue	Dandelion
Old man's whiskers	Cut leaved anemone
Silverberry	Rose



SITE CHARACTERISTICS

Moisture regime: submesic, mesic
Nutrient regime: rich, medium
Topographic position: crest, midslope, lower slope
Slope: (0-2%)[5](16-30%)[3] (31-45%)[1](45-70%)[1]
Aspect: south, southwest, west

SOIL CHARACTERISTICS

Organic thickness: (0-2)(2-5)
Humus form: mull
Surface texture: CL,SiL, L
Effective texture: CL, SiL, SL,
Depth to Mottles/Gley: none
Drainage: well
Parent material: F, GF, M
Soil subgroup: O.BL, O.DG, O.MB

COMMUNITY TYPES

SASMC8 Marsh reedgrass-Timothy/Cow parsnip/(n=1)

i fen (n=8)(taken from Ecosites of West-Central Alberta)

GENERAL DESCRIPTION

The rich and poor fen are combined in this ecosite. The fen ecosite is generally characterized by flowing oxygenated water and alkaline, nutrient-rich conditions. This ecosite occupies level, depressional and lower slope positions where impeded drainage or high water tables enhance the accumulation of organic matter consisting of sedges, golden moss, tufted moss, and brown moss. Black and/or Engelmann spruce dominate the canopy of the treed phase, while dwarf birch or willow form the canopy of the shrubby phase and sedges dominate the graminoid phase.

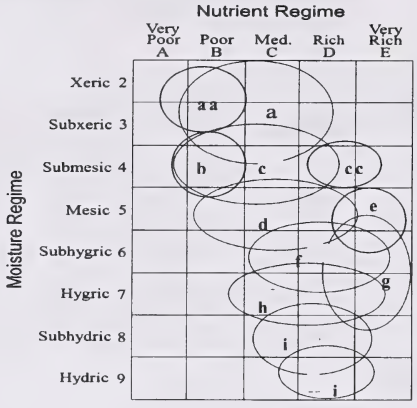
SUCCESSIONAL RELATIONSHIPS

The fen is an early stage in hydarch succession. Species composition, direction, and rate of succession changes with changing hydrologic regime. As with other wetlands, rich fens have slow successional rates so recovery from disturbance may also be slow.

INDICATOR SPECIES

Black spruce
Engelmann spruce
Willow
Labrador tea
Dwarf birch
Horsetail
Sedge
Golden moss
Brown moss
Tufted moss

subhydric/rich



SITE CHARACTERISTICS

Moisture regime: subhygric, hygric, subhydric,hydric
Nutrient regime: rich, very rich, medium
Topographic position: level, depression, toe
Slope: level, (0-1%)
Aspect: level, southerly, easterly

SOIL CHARACTERISTICS

Organic thickness: (>80)(60-79)
Humus form: mor, peaty mor
Surface texture: fibric, mesic
Effective texture: fibric, mesic
Depth to Mottles/Gley: not applicable
Drainage: imperfect, poor, very poor

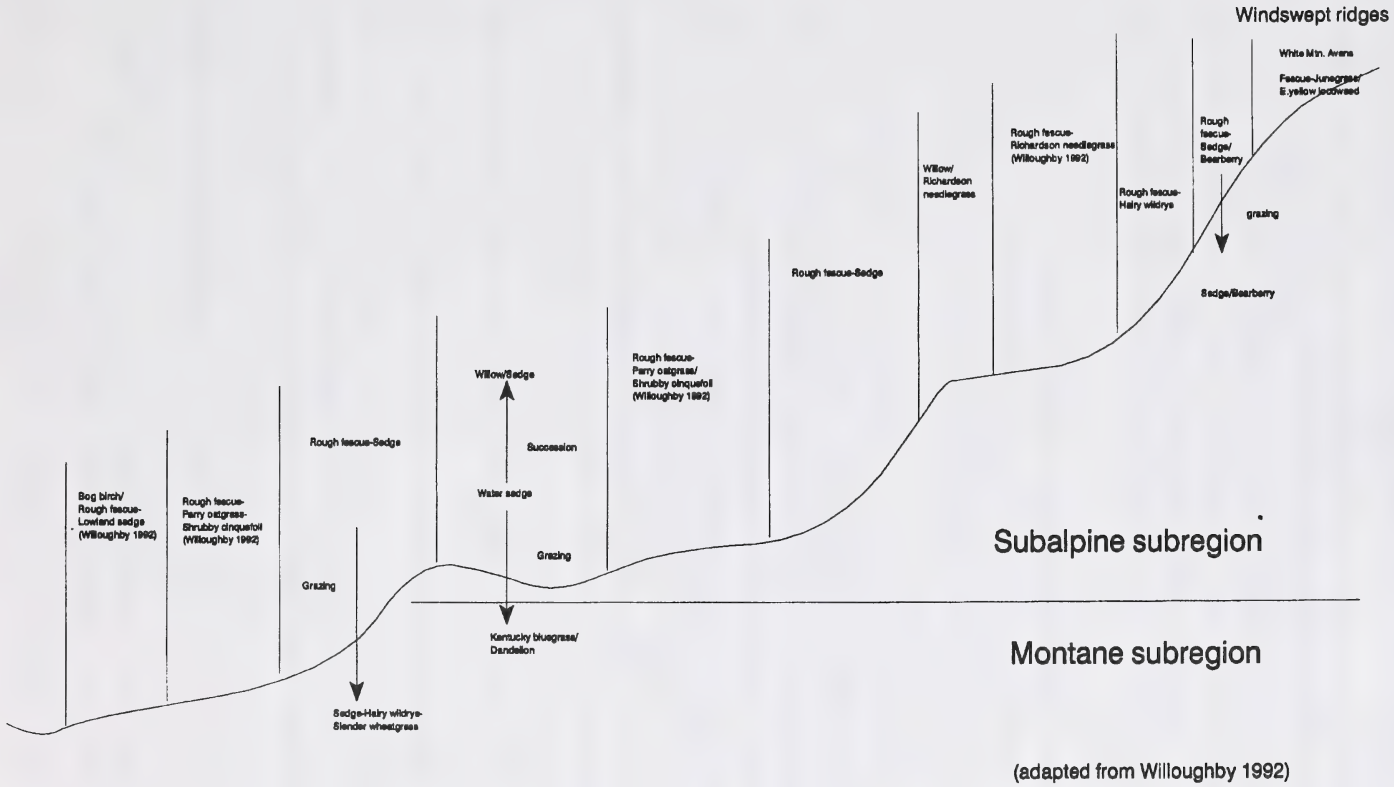

Figure 6. Sequence of grass and shrubland community types from the Montane to the Subalpine subregions of the Southern Rocky Mountain ecodistrict.

Key to grass and shrubland dominated communities in the Southern mountains of the Subalpine subregion.

1. Timberline communities or windswept ridges at timberline..... **2**
   Meadow communities or south facing grasslands at lower elevations..... **4**
2. Plant community dominated by Whitebark pine.....**SASMB3**
   Windswept ridges dominated by white mtn. avens, Idaho fescue or junegrass..... **3**
3. Community dominated by white mtn. avens.....**SASMA14**
   Grass dominated community dominated by Idaho fescue and Junegrass....**SASMA13**
4. Moist meadows or gravelly river flats dominated by shrubs, tufted hairgrass, sedge, yellow mtn. avens or silverberry..... **5**
   Drier south and north facing slopes dominated by rough fescue, parry oatgrass, upland sedges, hairy wildrye, pinegrass or forb dominated meadows with fireweed..... **13**
5. Dry gravelly river flats dominated by yellow mtn. avens or silverberry..... **6**
   Moist sites dominated by willow, bog birch or grassy areas dominated by tufted hairgrass, sedge, marsh reedgrass, kentucky bluegrass and dandelion..... **7**
6. Site dominated by yellow mtn. avens.....**SASMA6**
   Site dominated by silverberry.....**SASMA12**
7. Willow or bog birch dominated community types..... **8**
   Grass dominated meadows (tufted hairgrass, marsh reedgrass, alpine foxtail, beaked sedge, water sedge, kentucky bluegrass)..... **11**
8. Wetter sites dominated by sedge or marsh reedgrass in the understory..... **9**
   Drier, sites dominated by richardson needlegrass or rough fescue in understory..... **10**
9. Understory dominated by marsh reedgrass.....**SASMB5**
   Understory dominated by sedge.....**SASMB1**
10. Dry south facing slopes in Athabasca river valley near Jasper, dominated by Richardson needlegrass in understory.....**SASMB2**
    Understory dominated by rough fescue.....**SASMB4**
11. Very wet sites dominated by water sedge.....**SASMA1**
    Drier sites dominated by tufted hairgrass, graceful sedge, marsh reedgrass, alpine foxtail or Kentucky bluegrass.....**12**

12 Ungrazed sites dominated by tufted hairgrass, beaked sedge, alpine foxtail, marsh reedgrass, or graceful sedge.....**12a**
   Grazed sites dominated by Kentucky bluegrass, timothy or dandelion.....**12b**

12a Marsh reedgrass and cow parsnip dominated grassy meadows.....**SASMA7a**
   Tufted hairgrass, beaked sedge, alpine foxtail or graceful sedge dominated meadow.....**12c**

12b Marsh reedgrass, timothy, cow parsnip dominated meadows.....**SASMC8**
   Heavy grazing pressure site dominated by Kentucky bluegrass and dandelion.....**SASMA5**

12c Tufted hairgrass, graceful sedge dominated meadows.....**SASMA7**
   Beaked sedge, Alpine foxtail dominated meadow.....**SASMA1a**

13. Ungrazed rough fescue, hairy wildrye, pinegrass or forb dominated grasslands..... **14**
    Moderately to heavily grazed grasslands **20**
14. Pinegrass or forb (fireweed) dominated meadows **15**

Rough fescue, parry oatgrass, hairy wildrye, bearberry dominated grasslands..... **16**

15 Site dominated by forbs, moist seepage area.....**SASMA16**
Pinegrass, hairy wildrye dominated grassland.....**SASMA15**

16. Rough fescue dominated grasslands, south and west of Turner valley, hairy wildrye and sedge dominate or co-dominate grassland..... **17**
Rough fescue dominated grasslands, west of Porcupine Hills and in Castle area, co-dominated by Parry oatgrass, sedge or bearberry..... **18**

17. Grasslands of south facing slopes, sedge co-dominated..... **SASMA2**
Grasslands of lower slope positions or north aspects, dominated or co-dominated by hairy wildrye..... **17a**

17a Grassland dominated by hairy wildrye, north aspects on steep ridges.....**SASMA3a**
Grasslands co-dominated by hairy wildrye, south facing.....**SASMA3**

18. Grasslands of lower slope positions dominated by Rough fescue..... **SASMA8**
Grasslands of mid to upper slope positions dominated by Parry oatgrass, Idaho fescue or bearberry..... **19**

19. Grasslands of midslope position dominated by Parry oatgrass, Idaho fescue....**SASMA10**
Grasslands of upper slope positions or hillcrests co-dominated by bearberry....**SASMA9**

20. Moderately grazed grasslands native grass species still dominate the site..... **21**
Heavily grazed grasslands non-native species (Kentucky bluegrass, timothy, meadow foxtail) dominate or co-dominate the site..... **22**

21 Drier sites with bearberry **21a**
Moister sites dominated by sedge, hairy wildrye and slender wheatgrass.. **SASMA4**

21a Grassy areas with a high cover of Idaho fescue and Rough fescue.....**SASMC9**
Sedge dominates the grass layer.....**SASMA11**

22. Old range improvement dominated by meadow foxtail.....**SASMC3**
Meadow foxtail not present grazed sites..... **23**

23 Kentucky bluegrass or timothy dominated sites..... **24**
Kentucky bluegrass only co-dominate, Parry oatgrass or rough fescue or fringed sage dominates..... **25**

24. Timothy dominated community.....**SASMC7**
Kentucky bluegrass, dandelion dominated.....**SASMC6**

25. Rough fescue dominates the site..... **SASMC5**
Parry oatgrass or Fringed sage dominate the site..... **26**

26. Hillcrests and south facing slopes dominated by fringed sage.....**SASMC4**
Parry oatgrass dominated community types..... **27**

27. Parry oatgrass with Rough fescue and Kentucky bluegrass, lower slope.....**SASMC1**
Little rough fescue present, midslope position.....**SASMC2**

SASMA1. Water sedge

(Carex aquatilis)

n=4 This community type is found in all ecodistricts of the subalpine. Wet conditions and periodic flooding result in the formation of water sedge meadows. Willow will invade into the drier edges of these meadows to form the Willow/Water sedge community type. These community types are quite productive producing nearly 2000 kg/ha of forage, but the high water table in the spring and summer when these meadows are most palatable limits livestock use. A study in the Yukon found that crude protein on these meadows declined from a high of 10% in May to less than 5% in September (Bailey et al. 1992). As a result, these meadows would be rated as secondary or non-use range.

SASMA1a. Beaked sedge-Alpine foxtail-Tufted hairgrass

(Carex atherodes-Alopecurus occidentalis-Deschampsia cespitosa)

n=1 This community type was described in a meadow adjacent to a small creek. It is similar to the previously described water sedge community, but this community type is better drained which favours the growth of beaked sedge, alpine foxtail and tufted hairgrass. On the drier edges of this community type upland grass species like rough fescue and Idaho fescue can be found. Willoughby (1992) has found that beaked sedge is palatable to livestock, which causes these meadows to be regularly grazed. Heavy grazing will allow Kentucky bluegrass, timothy and dandelion to invade onto these sites.

SASMA2. Rough fescue-Sedge

(Festuca scabrella-Carex spp.)

n=23 This community type appears to be the modal grassland community type found on level and gentle south -facing slopes in the Southern Rocky Mountains of the Subalpine subregion. The dominance of rough fescue indicates that this grassland is transitional from the lower Montane subregion. As one moves up in elevation there is a shift away from a Rough fescue-Parry oatgrass dominated community type to a Rough fescue Sedge dominated community type. Willoughby (1992), found that blunt sedge replaced Parry oatgrass as dominant or codominant on steep south-facing slopes, and Richardson needlegrass replaced Parry oatgrass as codominant on more mesic sites in this area. This community type includes both the Rough fescue-Sedge, Rough fescue-Richardson needlegrass and Rough fescue-Parry oatgrass/Shrubby cinquefoil community types described by Willoughby (1992).

Jaques (1976), described a similar community type from Plateau Mountain to Mount Allan. He felt this community type represented critical wildlife habitat because it remained snow-free for a majority of the winter. Grazing by livestock on these community types should be managed carefully in order to maintain a carryover for wildlife in the winter.

SASMA3. Rough fescue-Hairy wildrye

(Festuca scabrella-Elymus innovatus)

n=9 This community is similar to the Rough fescue-Sedge community type (SASMA2) previously described, but it is found on drier, steeper slopes with poorer soils than the other rough fescue dominated community type. As one moves upslope there is a shift in codominance of sedge to hairy wildrye and an increase in cover of bearberry and juniper.

Corns and Achuff (1982), described hairy wildrye dominated community types on south facing slopes in the more northern ecodistricts. They felt these grasslands occurred on areas with frequent snow avalanching. It is possible that this community type is associated with deeper snow accumulation than the Rough fescue-Sedge dominated type previously described.

SASMA3a. Hairy wildrye- Rough fescue -Carex spp.

(Elymus innovatus- Festuca scabrella-Sedge)

n=1 This community is similar to the Rough fescue-Hairy wildrye community type (SASMA3) previously described, but this type was described on a site with a north aspect . Corns and Achuff (1982), described hairy wildrye dominated community types on south facing slopes in the more northern ecodistricts. They felt these grasslands occurred on areas with frequent snow avalanching. It would appear that this community type represents the transition between the northerly hairy wildrye dominated grasslands and the southerly rough fescue-hairy wildrye dominated grasslands.

This community type was described in an area that is difficult for livestock to access. It should likely be rated as non-use.

SASMA5. Kentucky bluegrass/Dandelion

(Poa pratensis/Taraxacum officinale)

n=14 This community type represents a moist, tufted hairgrass-sedge dominated community type that has been heavily grazed. Heavy grazing pressure causes tufted hairgrass to decline and allows sedge and Kentucky bluegrass to increase. Continuous heavy grazing pressure will eventually cause all native species to decline on the site and the site will become dominated by Kentucky bluegrass, dandelion and clover (Willoughby 1992).

SASMA6. Yellow mountain avens

(Dryas drummondii)

n=1 This is similar to the community type described in the Central and Northern Rocky Mountain ecodistricts. Corns and Achuff (1982) described this community type on recent fluvial and glacialfluvial landforms with gentle slopes, where the soils are rapidly drained. Willoughby et al. (2003), described a yellow mountain avens community on dry, gravelly river flats with nutrient poor soils in the Montane subregion. They found this community type to be successionally immature and succession would be to a Balsam poplar dominated community type.

SASMA7. Tufted hairgrass-Sedge

(Deschampsia cespitosa-Carex spp.)

n=3 This community type was described in the Savanna Creek range allotment and is located on moist sites that are better drained and slightly drier than the pure sedge meadows. Willoughby(2001), found that tufted hairgrass is a common plant species on lowland sites in the valley bottoms of the Upper Foothills subregion . Willoughby (1992), found when this community type is protected from grazing for 25-30 years, willow and bog birch expand and tufted hairgrass and sedge decline. The decline in graminoid cover also results in a decline in available forage production . Continuous heavy grazing causes hairgrass to decline and the site will be invaded by Kentucky bluegrass and dandelion.

SASMA7a. Marsh reedgrass/Cow parsnip

(Calamagrostis canadensis/Heracleum lanatum.)

n=1 This community type represents moist seepage areas in the foothills west of Turner valley. Often these sites are willow dominated to form the Willow/Marsh reedgrass dominated community type. Marsh reedgrass is characteristic of the lower elevation Lower Foothills subregion. Moving up in elevation into the Subalpine and Upper Foothills subregions, there is often a shift in dominance away from marsh reedgrass to tufted hairgrass on these moist sites. This community type is very similar to the Cow parsnip/Veiny meadow rue community described by Lane et al. (2000) in the Lower Foothills subregion. In the Lower Foothills this community type is very productive and is often heavily utilized by livestock. The Marsh reedgrass-Timothy/Cow parsnip (SASMC8) represents a grazing disclimax of this community type.

SASMA8. Rough fescue-Idaho fescue-Parry oatgrass

(Festuca scabrella-Festuca idahoensis-Danthonia parryii)

n=4 This community was described on lower slope positions in the Castle area. It is very similar to the Rough fescue-Idaho fescue-Parry oatgrass community described on Black Chernozemic soils in the Montane subregion from an elevation of 1300m up to 1900m (Willoughby et al. 2003) Willoughby (1992), described one Rough fescue-dominated site where the species composition had not changed in over 30 years, indicating this maybe the climax community type on river terraces and south facing slopes in the Montane subregion. Indeed Moss and Campbell (1947), found that rough fescue grows almost to the exclusion of other plants in the absence of disturbance. On rocky and gravelly slopes with shallow soils, rough fescue is replaced by Parry oatgrass and Idaho fescue. They also found Parry oatgrass and Idaho fescue increased and rough fescue declined with increased grazing pressure. Willoughby (1992), also described rough fescue and Idaho fescue dominated community types with little Parry oatgrass in the Castle area south of Blairmore. He also found that rose and shrubby cinquefoil tended to increase in cover at higher elevations in these grasslands.

SASMA9. Rough fescue-Sedge/Bearberry

(Festuca scabrella-Carex obtusaia./Arctostaphylos uva-ursi)

n=7 This community is characteristic of dry, south facing slopes, below the crest of the hill. It appears that snow accumulates in these areas favoring the growth of rough fescue. This community is similar to the Rough fescue-Sedge/Bearberry community type described by Willoughby et al. (2003) on hilltops in the Montane subregion. The shallow poorly developed soils appear to favour rough fescue, slender wheatgrass, and sedge over Parry oatgrass. This community is drier than the Rough fescue-Idaho fescue-Parry oatgrass grasslands characteristic of lower slope positions. This community type is similar to the Sedge/Bearberry community type but lacks the high cover of rough fescue. It appears that the Sedge/Bearberry community may represent a grazing disclimax of this community type.

SASMA10. Parry oatgrass-Rough fescue-Sedge

(Danthonia parryi-Festuca scabrella-Carex spp)

n=12 This community is situated upslope of the rough fescue dominated community types. This community type tends to be drier and better drained than the rough fescue dominated types found in the lower slope positions. The drier site conditions favour the growth of Parry oatgrass and sedge over rough fescue.

These sites are moderately productive and are easily accessible to livestock. They should be considered primary range. Continuous heavy grazing pressure will lead to a community type that is dominated by sedge and fringed sage.

SASMA12. Silverberry-Rose

(Elaeagnus commutata-Rosa acicularis)

n=1 This community type was described on the downwind side of the hill at lower elevations in the Castle area of the province (north of Waterton Lakes National Park). It appears this area accumulates snow so the moisture regime is favorable for the growth of silverberry and aspen. At 1800 m aspen is at its upper elevational limit. The aspen trees at this site are very stunted and lack the vigour of lower elevation sites. Silverberry is well adapted to growing on dry, gravelly, light soils in ravines, coulees and stream banks throughout Alberta (Wilkinson 1990). It is unusual to have silverberry and aspen growing at these higher elevations indicating that this site is somewhat protected and warmer so that the climate resembles the lower elevation sites.

SASMA13. Fescue-Junegrass/Early yellow locoweed

(Festuca spp.-Koeleria macrantha/Oxytropis sericea)

n=17 This community type is characteristic of the dry, rocky, windswept ridges in the Castle area north of Waterton Lakes National Park. At higher elevations this community is often replaced by the White mountian avens community which occupies similar sites. This community type is somewhat variable false mountain dandelion and early yellow locoweed were found in the majority of the plots, but in areas where there is slightly more snow accumulation the cover of Idaho fescue increases, and there are larger patches of species like spotted saxifrage, brown bracted mountian everlasting and sandwort. Bareground on these moister areas is usually less than 40%. In contrast bareground on the drier parts of this community type exceed 60%. At lower elevations on Whistler Mtn. bluebunch wheatgrass becomes more prevalent.

SASMA14. White mountain avens

(Dryas octopetala)

n=12 This community occurs on wind-exposed, snow free ridges and resembles the White mountain avens community described in the Alpine subregion. The soils are shallow, stoney, colluvial Regosols (Corns and Achuff 1982). Ogilvie (1969), found this community type to have an abundance of cushion and mat plants and a large number of lichens. This community is generally found at higher elevations than the Fescue-Junegrass/E. yellow locoweed community type. This community type appears to have no snow accumulation throughout the year, whereas, the fescue, Junegrass dominated community appears to have some snow accumulation. This may account for the differences in dominant plant species for each community type.

SASMA15. Pinegrass-Hairy wildrye/Strawberry

(Calamagrostis rubescens-Elymus innovatus/Fragaria virginiana)

n=4 This community type is similar to the pinegrass dominated community type described on west and north facing slopes in the Montane subregion (Willoughby et al 2003). In the Montane this community represents the transition from grassland to forest on moist sites with northerly aspects. There is usually high forb cover on these sites with strawberry, showy aster, american vetch and silkly perennial lupine being common. Pinegrass and Hairy wildrye are common grass species in the understory of conifer and deciduous stands and their dominance in this community type may indicate a transition to a forested community. The higher moisture conditions on these sites allows for production of over 2000 kg/ha.

SASMA16. Forb meadow

(Epilobium angustifolium)

n=3 This site is similar to the Fireweed-Meadow rue/Sedge dominated community type described in the northern foothills area of the Subalpine. This community is characterized by a dominance of forb species (fireweed, graceful cinquefoil, yellow hedysarum) and only a small cover of grass species. It would appear that the moisture and nutrient regime are higher on this site compared to the other grassland community types which favors the growth of forb species. Succession in the absence of disturbance will likely be to aspen and then white spruce.

The forage production of this community type is fairly high because of the higher moisture and nutrient content of the soil, but the areas are so small and isolated they contribute little to the overall carrying capacity of a disposition.

SASMB1. Willow/Sedge

(Salix spp./Carex spp.)

n=2 Willow encroachment into moist grassland meadows eventually results in this community type. Historically fire has played an important role in the maintenance of the grassland community type in this subregion. Continued fire suppression will eventually allow willow and bog birch to invade many of the grassy meadows.

This community type is slightly drier than the Willow/Water sedge dominated community type.

SASMB4. Willow-Bog birch/Rough fescue-Kentucky bluegrass

(Salix spp.-Betula glandulosa\Festuca scabrella-Poa pratensis)

n=1 This community type represents the inside transect of a rangeland reference area which has been protected from grazing for over 30 years. This community type represents moist meadows and grasslands in the Sheep area west of Turner valley. Continous heavy grazing pressure will cause the cover of shrubs and rough fescue to decline and allow Kentucky bluegrass, timothy and dandelion to invade onto the site.

This area of the province is classified as Lower Foothills (Alberta Environmental Protection 1994), but the plant species of this area are more characteristic of the Parkland and Montane subregions and the higher Subalpine subregion than the Lower Foothills. As a result this community type was placed within the Subalpine subregion guide.

ENVIRONMENTAL VARIABLES

SASMB5. Willow/Marsh reedgrass

(Salix spp./Calamagrostis canadensis)

n=2 This community type was described in the Pekisko and Deep Creek allotments which are southwest of Longview. This community represents a small pocket of willow in depressional and seepage areas. It is unusual having a community type dominated by marsh reedgrass in the Subalpine subregion. Marsh reedgrass is more characteristic of wetland sites in the Boreal forest and Lower Foothills subregions of North and Central Alberta. Perhaps this community represents a transition between the Subalpine and lower elevation Montane subregion.

These sites can be highly productive because of the increased moisture and nutrients at the site, but livestock will rarely use these communities and they should be considered non-use.

SASMC1. Parry oatgrass-Rough fescue-Kentucky bluegrass

(Danthonia parryii-Festuca scabrella-Poa pratensis)

n=7 This community type represents the grazing disclimax community of the Rough fescue-Idaho fescue-Parry oatgrass community type. Increased grazing pressure favours the growth of Parry oatgrass and sedge over rough fescue. Continued heavy grazing pressure eventually leads to a decline in all native species and the site is often dominated by only Kentucky bluegrass, timothy and dandelion. Recovery of this community type back to a rough fescue dominated site is possible with a reduction in grazing pressure, but once Kentucky bluegrass establishes in the stand it will likely remain as a co-dominant.

This community type is very productive and should be considered primary range.

SASMC2. Parry oatgrass-Kentucky bluegrass-Sedge

(Danthonia parryi-Poa pratensis-Carex spp.)

n=4 This community type represents a heavily grazed Parry oatgrass-Rough fescue-Sedge community type. Heavy grazing pressure favours the growth of grazing resistant species of Kentucky bluegrass and sedge and causes rough fescue to decline. Continued heavy grazing pressure will eventually lead to a community type that is dominated by Kentucky bluegrass, timothy and sedge. If the grazing pressure is reduced on this community type there is a good possibility of recovery.

SASMC3. Meadow foxtail-Kentucky bluegrass

(Alopecurus pratensis-Poa pratensis)

n=3 This community type was described in the South Sheep allotment. It represents small aspen stands that were cleared and seeded to a mixture of meadow brome, creeping red fescue, clover and meadow foxtail. These sites have continued to be heavily grazed which has favoured the growth of meadow foxtail, Kentucky bluegrass and clover. Meadow foxtail is not particularly palatable to livestock and therefore gains a competitive advantage over meadow brome and creeping red fescue, in these seeded areas.

SASMC4. Fringed sage/Kentucky bluegrass-Sedge

(Artemisia frigida/Poa pratensis-Carex spp.)

n=1 This community type was described on a south facing slope and ridge top in the South Sheep allotment. It appears to represent long-term heavy grazing pressure on a Parry oatgrass-Rough fescue-Sedge dominated community type. The increased grazing pressure on these south facing slopes favours the growth of fringed sage, sedge, Kentucky bluegrass and dandelion. It is unusual having such a high cover of Kentucky bluegrass on these slopes. Kentucky bluegrass usually prefers moister lower slope positions. Perhaps the higher precipitation received in the Subalpine subregion compared to the Montane makes the south facing slopes more favorable to Kentucky bluegrass invasion.

There is still a strong component of native species in this community type and recovery is likely if the grazing pressure is reduced.

SASMC5. Rough fescue-Kentucky bluegrass

(Festuca scabrella-Poa pratensis)

n=1 This community type was described in the South Sheep allotment west of Turner valley and represents a rough fescue grassland that has been heavily grazed to the point of Kentucky bluegrass invasion and is now recovering. Long-term heavy grazing pressure leads to a decline in rough fescue and an increase in Parry oatgrass and sedge species. Continued grazing pressure reduces the competitive advantage of rough fescue and the other native grass species and allows Kentucky bluegrass to establish on site. Protection or a reduction in stocking level at the point where Kentucky bluegrass becomes a significant of the community allows rough fescue to recover, but it seems Kentucky bluegrass also remains as co-dominant.

SASMC6. Kentucky bluegrass-Rough fescue

(Poa pratensis-Festuca scabrella)

n=13 Long-term heavy grazing pressure leads to a decline in rough fescue and an increase in Parry oatgrass and sedge species. Continued grazing pressure reduces the competitive advantage of rough fescue and the other native grass species and allows Kentucky bluegrass to establish on site. Continued heavy grazing pressure eventually leads to a decline in all native species and the plant community will resemble a Timothy-Kentucky bluegrass/dandelion type.

The forage productivity of this community type (2300 kg/ha) is equivalent to or better than a lightly grazed Rough fescue dominated community (1900 kg/ha). However, rough fescue is a more desirable forage species because it maintains it nutrient content into the dormant season. In contrast, Kentucky bluegrass loses its palatability and nutrient content if is allowed to flower and set seed.

SASMC7. Timothy-Kentucky bluegrass/Dandelion

(Phleum pratense-Agropyron trachycaulum/Epilobium angustifolium)

n=8 This community type was described in moist lower slope positions. Heavy grazing pressure has caused the native grass species to decline and allowed Canada bluegrass and timothy to invade onto the site. The presence of fireweed indicates that the site will likely succeed to an aspen dominated community type.

This community type is highly productive and it is easily accessible to domestic livestock. It should be rated as primary range.

SASMC8. Marsh reedgrass-Timothy/Cow parnsip

(Calamagrostis canadensis-Phleum pratense/Heracleum lanatum)

n=1 This community type represents seepage areas in the foothills west of Turner valley. Often these areas are invaded by willow to form the Willow/Marsh reedgrass dominated community type. This community type is very similar to the Marsh reedgrass/Cow parnsip community previously described, but this community has a high cover of timothy. Timothy, Kentucky bluegrass and dandelion will often invade these sites when exposed to heavy grazing pressure. This community type is highly productive and should be rated as primary range.

Figure 7. Deciduous communities are not common in the Subalpine, but where they do occur they can be very productive for domestic livestock. This picture represents an Aspen/Rose/Pinegrass dominated community, which can be common on warmer sites in the Subalpine subregion of southern Alberta.

SUBALPINE SUBREGION

FOREST ECOLOGY

The forested plant communities in the subalpine can be split into three zones. These include the Pine, Spruce-Fir and Upper Subalpine zones (Strong and Leggat 1992). The Pine zone is the lowest elevation zone and is dominated by lodgepole pine and shows little evidence of succession to Engelmann spruce. It is within this zone that aspen and balsam poplar dominated plant communities can occur on warmer sites. The Spruce-Fir zone is located altitudinally above the Pine zone (Strong and Leggat 1992). This zone displays evidence of lodgepole pine succession to Engelmann spruce and subalpine fir. The Upper subalpine zone is characterized by open canopied vegetation that occurs between the Spruce-Fir zone and timberline. This zone is dominated by dwarfed Engelmann spruce, alpine fir, whitebark pine and alpine larch. Plant growth in this upper zone is limited by low temperatures, wind, low moisture and a short growing season (Strong and Leggat 1992). There are only a handful of forested community types described in this guide. Archibald et al. (1996), provide a good descriptions of the major forested community types in the Subalpine subregion that are not represented in this guide. Generally, these forested plant communities only provide limited forage for domestic livestock, but where deciduous communities are extensive they can be heavily utilized by livestock and should be considered secondary range.

SASMD1. Pb/Silverberry

(Populus balsamifera/Elaeagnus commutata)

n=1 This community type was described along the banks of Pekisko creek in the Pekisko Creek allotment. It is characteristic of dry gravelly, river flats, which are periodically flooded in the spring. This community type is very similar to the yellow mountain avens community which have been described in both the Montane and Subalpine subregions.

Generally, there is little forage for domestic livestock in this community type and it should be rated as non-use.

SASMD2. Aw/Rose/Pinegrass

(Populus tremuloides/Rosa/Calamagrostis rubescens)

n=20 This community type is similar to the Aw/Rose/Pinegrass community which is described on mesic sites with medium nutrient regimes in the Montane subregion. It may represent the transition from the Montane to the Subalpine. These sites were described at lower elevations in the Subalpine and generally had southerly aspects, making the conditions more suitable for growing aspen. The forage productivity on this community type is moderate and it should be rated as secondary range.

SASMD3. Aw/Fireweed/Meadow foxtail

(Populus tremuloides/Epilobium angustifolium/Alopecurus pratensis)

n=1 This community type was described in the South Sheep allotment on an old range improvement area. Many aspen stands in the South Sheep were cleared and seeded to mixture of brome, meadow foxtail, creeping red fescue and clover. This site represents invasion of aspen back into these range improvement areas. Meadow foxtail is generally unpalatable to livestock and has persisted on these sites.

This community is very productive and efforts should be made to control the aspen invasion.

SASMD4. Aw/Rose/Canada bluegrass

(Populus tremuloides/Rosa spp./Poa compressa)

n=1 This community type represents a Aw/Rose/Pinegrass community that has been heavily grazed and invaded by Canada bluegrass. Canada bluegrass is an introduced grass that increases with increased grazing pressure. As grazing pressure increases in these aspen dominated community types there is a shift away from native species (rose, pinegrass, asters, fireweed) to a community that is dominated by bluegrass, timothy, dandelion and clover species. The invasion of non-native invaders onto the site makes this community very productive for domestic livestock, but the presence of overgrazed communities indicates some type of distribution problem and the management of the disposition should be discussed.

SASMD6. Aw-Pb/Cow parsnip/Timothy

(Populus tremuloides-Populus balsamifera/Heracleum lanatum/Phleum pratense)

n=1 Nutrient seepage occurs at some point in the growing season favouring the growth of cow parsnip. This community type is very similar to the previously described Aw-Pb/Cow parsnip community, but this community has a high cover of timothy. Increased grazing pressure will often allow timothy, Kentucky bluegrass and dandelion to invade onto these sites. Forage productivity on these sites is generally quite high because of the favourable moisture and nutrient conditions. Cow parsnip is palatable to livestock and maybe extensively utilized. This community type should be rated as secondary range.

SASME1. Pl/Juniper

(Pinus contorta/Juniperus spp.)

n=1 Dry site conditions from south exposures or coarse textured soils are characteristic of this community type (Archibald et al. 1996). The dry site conditions limit the amount of forage this site can produce and the steep slope limits access to livestock. As a result, this community would be considered non-use.

ENVIRONMENTAL VARIABLES

SASME2. Pl/Pinegrass

(Pinus contorta/Calamagrostis rubescens)

n=1 This community type is very similar to the Pl/Pinegrass dominated community described in the Montane subregion (Willoughby et al. 2003). Succession will be to white spruce, but the extensive fire history in the area has resulted in a predominance of lodgepole pine (Archibald et al 1996). Pinegrass is generally unpalatable to livestock, but if grazed early in the spring they will utilize it as a forage source. The forage productivity of this community type is quite low. As a result this community type should be rated as non-use.

SASME3. Pl-Se/Moss

(Pinus contorta-Picea engelmannii/Moss spp.)

n=5 This community type represents the modal conditions for the Subalpine subregion at mid to lower elevations. Lodgepole pine, Engelmann spruce and subalpine fir can all occur as the dominant tree species on this ecological site. In general succession is from lodgepole pine to Engelmann spruce and subalpine fir. However, lodgepole pine is the most common tree species because of the frequency of fire.

There is little forage for domestic livestock in this community type. As a result, this community should be rated as non-use.

ALPINE SUBREGION

NATIVE GRASSLANDS AND SHRUBLANDS

Figure 8. Low growing plant communities of white mountain avens and bog sedge on windswept ridges, with arctic willow, heather and blackening sedge in snow accumulation areas are typical of the Alpine subregion

Alpine communities

The alpine environment generally occurs above timberline. Ogilvie (1969), found timberline to be controlled by low temperature, wind dessication, avalanching and snow depth. The alpine plants and communities show adaptations to these extreme environmental conditions. The alpine plant communities tend to be low growing where they are protected from the wind and benefit from the warmer temperatures close to the ground (Ogilvie 1969). Figure 4 outlines the alpine communities in the landscape of the Rocky Mountains. On south facing, wind swept ridges the bog sedge and white dryad communities are found. At slightly lower elevations where snow accumulates the low growing willow communities predominate (arctic willow, snow willow, rock willow). On the north facing slopes where snow accumulates the blackening sedge and heather community types are found. In the valley bottoms below timberline the willow, bog birch, and grassy meadow community types are typical. The sequence of the valley bottom community types in the landscape is described in Figure 2. The plant community types found in the Alpine subregion are listed in Table 7.

Many of these alpine grass and shrublands are very fragile because of exposure and cold climate. The forage productivity is very low compared to the valley bottoms. Consequently, recovery from overgrazing will likely take some time. As a result grazing by domestic livestock in the Alpine subregion should be discouraged.

Table 7. Native grass and shrublands of the Alpine subregion
